TWO-DIMENSIONAL STABILITY ANALYSIS IN A HIV MODEL WITH QUADRATIC LOGISTIC GROWTH TERM

CLAUDE-MICHEL BRAUNER, XINYUE FAN, AND L. LORENZI

Abstract. We consider a Human Immunodeficiency Virus (HIV) model with a logistic growth term and continue the analysis of the previous article [6]. We now take the viral diffusion in a two-dimensional environment. The model consists of two ODEs for the concentrations of the target T cells, the infected cells, and a parabolic PDE for the virus particles. We study the stability of the uninfected and infected equilibria, the occurrence of Hopf bifurcation and the stability of the periodic solutions.

1. Introduction

Over the past thirty years, there has been much research in the mathematical modeling of Human Immunodeficiency Virus (HIV), the virus which causes AIDS (Acquired Immune Deficiency Syndrome). The research directions have been twofold: (i) the epidemiology of AIDS; (ii) the immunology of HIV as a pathogen. We are interested in the latter approach.

The major target of HIV infection is a class of lymphocytes, or white blood cells, known as CD4$^+$ T cells. When the CD4$^+$ T-cell count, which is normally around 1000 mm^{-3}, reaches 200 mm^{-3} or below in an HIV-infected patient, then that person is classified as having AIDS.

Mathematical models have been proved valuable in understanding the in vivo dynamics of the virus. A gamut of models have been developed to describe the immune system, its interaction with HIV, and the decline in CD4$^+$ T cells. They have contributed significantly to the understanding of HIV basic biology.

Recently, the effect of spatial diffusion has been taken in account in HIV modeling. Funk et al. [7] introduced a discrete model: they adopted a two-dimensional square grid with 21×21 sites and assumed that the virus can move to the eight nearest neighboring sites. K. Wang et al. [18] generalized Funk's model. They assumed that the hepatocytes can not move under normal conditions and neglected their mobility, whereas virions can move freely and their motion follows a Fickian diffusion. In [1], two of the authors considered a two-dimensional heterogenous environment: the basic reproductive ratio is generalized as an eigenvalue of some Sturm-Liouville problem. Furthermore, in the case of an alternating structure of viral sources, the classical approach via ODE systems is justified via a homogenized limiting environment.

In this article, we consider a HIV model which takes the viral diffusion into account in a homogeneous two-dimensional environment, and includes a quadratic logistic growth term as previously proposed in [16, 17] to consider the homeostatic process for the CD4$^+$ T-cell count. The model reads:

$$\frac{\partial T}{\partial t} = \alpha - \mu_T T + rT\left(1 - \frac{T}{T_{\max}}\right) - \gamma VT, \tag{1.1}$$

$$\frac{\partial I}{\partial t} = \gamma VT - \mu_I I, \tag{1.2}$$

Key words and phrases. HIV, stability, Hopf bifurcation.

This work was partially supported by a grant of the Fujian Administration of Foreign Expert Affairs, China.

$$\frac{\partial V}{\partial t} = N\mu_I I - \mu_V V + d_V \Delta V. \tag{1.3}$$

The spatial domain is denoted by $\Omega_\ell = (0,\ell) \times (0,\ell)$, periodic boundary conditions are prescribed for V. Since the system (1.1)-(1.3) defines a dynamical system or semiflow, we will also use the abstract notation $\mathbf{X}(t) = (T(t), I(t), V(t))$.

Our aim is to continue the analysis of the previous paper [6], where we studied the system (1.1)-(1.3) when $d_V = 0$. We refer to [6] for an extended introduction to the biological issues. In brief, we recall that T and I denote the respective concentrations of uninfected and infected CD4$^+$ T cells. The concentration of free virus particles, or virions, is V (for the sake of simplicity, we call V the virus). In (1.1), r is the average specific T-cell growth rate obtained in the absence of population limitation. The term $1 - T/T_{\max}$ shuts off T-cell growth as the population level $T_{\max}$ is approached from below. Here μ_T is the natural death rate of CD4$^+$ T cells, the term γVT models the rate at which free virus infects a CD4$^+$ T cell. The infected cells die at a rate μ_I and produce free virus during their life-time at a rate N. In addition, μ_V is the death rate of the virus. According to the literature (see e.g., Table 1 or [2] where $\mu_T = 0.01$, $\mu_I = 0.39$), we assume the following biologically relevant hypothesis:

$$\mu_I > \mu_T. \tag{1.4}$$

Note that the quantity $r - \mu_T$, the net T-cell proliferation rate, needs not to be positive (see [16, p. 86]).

Table 1. Parameters and Variables

	Parameters & Variables	Values
Dependent variables		
T	Uninfected $CD4^+$ T-cell population	mm^{-3}
I	Infected $CD4^+$ T-cell density	mm^{-3}
V	HIV population size	mm^{-3}
Parameters & Constants		
r	Proliferation rate of the $CD4^+$ T-cell population	0.2 day^{-1}
N	Number of virus produced by infected cells	1000
α	Production rate for uninfected $CD4^+$ T cells	1.5 $day^{-1}mm^{-3}$
γ	Infection rate of uninfected $CD4^+$ T cells	0.001 $day^{-1}mm^{3}$
$T_{\max}$	Maximal population level of $CD4^+$ T cells at which the $CD4^+$ T-cell proliferation shuts off	1500 mm^{-3}
μ_T	Death rate of uninfected $CD4^+$ T-cell population	0.1 day^{-1}
μ_I	Death rate of infected $CD4^+$ T-cell population	0.5 day^{-1}
μ_V	Clearance rate of free virus	10 day^{-1}
Derived variable		
T_0	$CD4^+$ T-cell population for HIV negative persons	mm^{-3}

From a mathematical viewpoint:
(i) $N > 0$ and $r \geq 0$ are parameters;
(ii) the quantities (with associated dimension) $\alpha, \gamma, \mu_I, \mu_T$ and μ_V are fixed positive numbers throughout the paper;
(iii) $T_{\max}$ is a large perturbation parameter, larger than any finite combination of $\alpha, \gamma, \mu_I, \mu_T$ and μ_V of the same dimension (mm^{-3}). In particular, this hypothesis contains the condition $T_{\max} > \alpha/\mu_T$ of [16, p. 85].

The paper is organized as follows: in Section 2, we prove that System (1.1)-(1.3) admits, for any value of the parameters r and N, the uninfected steady state $\mathbf{X}_u = (T_u, 0, 0)$ and that, in a region of the space of parameters, there exists also another steady-state solution, the so-called infected steady state $\mathbf{X}_i = (T_i, I_i, V_i)$, where T_i, I_i and V_i are positive. In the parameter space, we define the regions $\mathcal{U}$ and $\mathcal{I}$ (this latter being the region where the infected steady-state exists), respectively for uninfected (the reproductive ratio is such that $R_0 < 1$) and infected ($R_0 > 1$). We recall that the basic reproductive ratio denotes the average number of infected T cells derived from one infected T cell ([4]). We prove that the uninfected steady state is asymptotically stable in $\mathcal{U}$, and unstable in $\mathcal{I}$.

In [6], we have exhibited an unbounded subdomain $\mathcal{P}$ in $\mathcal{I}$ in which the positive infected equilibrium becomes unstable whereas it is asymptotically stable in the rest of $\mathcal{I}$. In this unstable region, the levels of the various cell types and virus particles oscillate, rather than converging to steady values. This subdomain $\mathcal{P}$ may be biologically interpreted as a perturbation of the infection by a specific or unspecific immune response against HIV. In Section 3, we consider the linearization around $\mathbf{X}_i = (T_i, I_i, V_i)$ of System (1.1)-(1.3) with Jacobian matrix $\mathscr{L}_i$. A modal expansion of the resolvent equation enables us to construct a *finite number* of subdomains $\mathcal{P}_k$ ($k = 0, \ldots, K_2$) in $\mathcal{I}$, that form a monotone non-increasing sequence (for the inclusion) with $\mathcal{P}_0 = \mathcal{P}$. It turns out that the infected equilibrium $\mathbf{X}_i = (T_i, I_i, V_i)$ is asymptotically stable for $(N, r) \in \mathcal{I} \setminus \mathcal{P}$ and unstable in the interior of $\mathcal{P}$. Therefore the stability issue is governed by the 0-th mode, hence similar to the case without viral diffusion ($d_V = 0$). As a matter of fact, we are unable to confirm Funk et al. [7], who suggested that the presence of a spatial structure enhances population stability with respect to non-spatial models (see also [1]).

In Section 4, we take the logistic parameter r as bifurcation parameter and prove the existence of Hopf bifurcations at the boundary $\partial\mathcal{P}$. Since the system is only partially dissipative, the resolvent operator associated to the realization L_i of $\mathscr{L}_i$ is not compact and therefore the proof demands more attention: it relies on the analyticity of the semigroup $\exp(tL_i)$ (see e.g., [10], [15]). Next, we perform a nonlinear analysis at the Hopf points via the Center Manifold theorem. It turns out that the bifurcating periodic solutions are independent of the space variables.

Numerical illustrations are presented in Section 5. Finally, for the sake of completeness, we recall in an Appendix some basic facts about the eigenvalues of the two-dimensional Laplace operator with periodic boundary conditions and some Sturm-Liouville operators.

Notation. For any $\ell > 0$ we denote by L^2 the usual space of square-integrable functions $f : (0, \ell)^2 \to \mathbb{R}$. The square $(0, \ell)^2$ will be simply denoted by Ω_ℓ. By $H^k_\sharp$ ($k = 1, 2, \ldots$) we denote the closure in H^k (the subset of L^2 of all the functions whose distributional derivatives up to k-th order are in L^2) of the space $C^k_\sharp$ of all k-th continuously differentiable functions $f : \mathbb{R}^2 \to \mathbb{R}$ which are periodic with period ℓ in each variable. The space $H^k_\sharp$ is endowed with its Euclidean norm. If X is any of the previous spaces, we write $X_\mathbb{C}$ to denote the space of complex-valued functions f such that $\mathrm{Re}\, f$ and $\mathrm{Im}\, f$ are in X. The norm in $X_\mathbb{C}$ is defined in the natural way: $\|f\|^2_{X_\mathbb{C}} = \|\mathrm{Re}\, f\|^2_X + \|\mathrm{Im}\, f\|^2_X$. If $\mathbf{v}$ is a vector of $\mathbb{C}^3$, we denote by v_1, v_2 and v_3 its components. Similarly, if $\mathbf{f}$ is a function defined in Ω_ℓ with values in $\mathbb{R}^3$ (resp. $\mathbb{C}^3$), we denote by f_1, f_2 and f_3 its components. If the components of the vector $\mathbf{v}$ are complex numbers, we denote by $\overline{\mathbf{v}}$ the vector whose components are the conjugates of the components of $\mathbf{v}$. The Euclidean inner product in $L^2_\mathbb{C} \times L^2_\mathbb{C} \times L^2_\mathbb{C}$ is denoted by $(\cdot, \cdot)_2$, i.e.,

$$(\mathbf{f}, \mathbf{g})_2 = \int_{\Omega_\ell} (f_1\overline{g_1} + f_2\overline{g_2} + f_3\overline{g_3})\,dxdy,$$

for any $\mathbf{f}, \mathbf{g} \in L^2_\mathbb{C} \times L^2_\mathbb{C} \times L^2_\mathbb{C}$. Finally, we denote by Id the identity operator, and by $(\cdot)^+$ the positive part of the number in brackets.

2. Equilibria

In this section we are devoted to determine the non-negative equilibria of System (1.1)-(1.3), i.e., the solutions $(T, I, V) \in L^2 \times L^2 \times H^2_\sharp$ to the system

$$\alpha - \mu_T T + rT\left(1 - \frac{T}{T_{\max}}\right) - \gamma VT = 0, \tag{2.1}$$

$$\gamma VT - \mu_I I = 0, \tag{2.2}$$

$$N\mu_I I - \mu_V V + d_V \Delta V = 0. \tag{2.3}$$

To state the first main result of this section, let us introduce some functions and a few notation.

By $\mathbf{X}_u$ and $\mathbf{X}_i$ we denote, respectively, the function whose entries T_u, I_u and V_u are given by

$$T_u = T_0, \qquad I_u = 0, \qquad V_u = 0,$$

where

$$T_0 = T_0(r) = \frac{r - \mu_T + \sqrt{(r-\mu_T)^2 + \frac{4\alpha r}{T_{\max}}}}{2r} T_{\max},$$

and the function whose entries are given by T_i, I_i and V_i, where

$$\begin{aligned} T_i &= \frac{\mu_V}{\gamma N}, \\ I_i &= \frac{\alpha}{\mu_I} - \frac{\mu_T \mu_V}{\gamma \mu_I N} + \frac{\mu_V r}{\gamma \mu_I N}\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right), \\ V_i &= \frac{\alpha N}{\mu_V} - \frac{\mu_T}{\gamma} + \frac{r}{\gamma}\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right). \end{aligned}$$

We further introduce two sets which will play a fundamental role in all our analysis, namely the uninfected and infected regions $\mathfrak{U}$ and $\mathfrak{I}$ in the parameter space, which are defined by

$$\mathfrak{U} = \{(N, r) : N > 0,\ r \geq 0,\ R_0(N, r) < 1\}, \qquad \mathfrak{I} = \{(N, r) : N > 0,\ r \geq 0,\ R_0(N, r) > 1\},$$

where

$$R_0(N, r) = \frac{\gamma N T_0(r)}{\mu_V}$$

is the reproduction ratio.

The interface $R_0(N, r) = 1$ between the two regions $\mathfrak{U}$ and $\mathfrak{I}$ is the graph of the mapping

$$N_{\mathrm{crit}}(r) = \frac{\mu_V\left(\mu_T - r + \sqrt{(\mu_T - r)^2 + \frac{4\alpha r}{T_{\max}}}\right)}{2\alpha\gamma} = \frac{\mu_V}{\gamma T_0(r)}, \tag{2.4}$$

which is decreasing by virtue of the condition $T_{\max} > \alpha\mu_T^{-1}$. Its image is the interval $\left(\frac{\mu_V}{\gamma T_{\max}}, \frac{\mu_T \mu_V}{\alpha\gamma}\right]$. Inverting the roles of N and r, it is useful to define the inverse mapping:

$$r_{\mathrm{crit}}(N) = \frac{(\mu_T \mu_V - \alpha\gamma N)^+}{\mu_V\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)}, \qquad N > N_{\mathrm{crit}}(+\infty) = \frac{\mu_V}{\gamma T_{\max}}.$$

As it has been stressed in the introduction, throughout the paper we assume that

$$\mu_I > \mu_T. \tag{2.5}$$

To prove the following theorem we assume also that

$$T_{\max} \geq T^0_{\max}(\alpha, \gamma, \mu_I, \mu_T, \mu_V), \tag{2.6}$$

where $T^0_{\max}$ is fixed and large, and depends only on the quantities in brackets.

Theorem 2.1. *The following properties are satisfied:*

(i) *in* $\mathcal{U}$ *the uninfected steady state* $\mathbf{X}_u = (T_u, I_u, V_u)$ *is the only non-negative equilibrium;*

(ii) *in* $\mathcal{I}$ *there exist two non-negative equilibria, respectively* $\mathbf{X}_u$ *and the infected steady state* $\mathbf{X}_i = (T_i, I_i, V_i)$*;*

(iii) *it holds* $0 < T_u < T_{\max}$ *and, in* $\mathcal{I}$, $0 < T_i < T_{\max}$*;*

(iv) $\mathbf{X}_u$ *and* $\mathbf{X}_i$ *are all the possible equilibria to System* (1.1)-(1.3), *with all the components being non-negative.*

Proof. (i) Suppose that $\mathbf{X} = (T, I, V)$ is a solution to System (2.1)-(2.3). Then, from (2.1) we deduce that

$$T = \frac{r - \mu_T - \gamma V + \sqrt{(r - \mu_T - \gamma V)^2 + \frac{4\alpha r}{T_{\max}}}}{2r} T_{\max}. \tag{2.7}$$

Replacing the expression of I given by (2.2) in (2.3) and, then, using (2.7), we obtain the following self-contained nonlinear equation for V:

$$d_V \Delta V - \mu_V V + \Phi(V) = 0, \tag{2.8}$$

where

$$\Phi(V) = \frac{\gamma N V}{2r}\left(r - \mu_T - \gamma V + \sqrt{(r - \mu_T - \gamma V)^2 + \frac{4\alpha r}{T_{\max}}}\right) T_{\max}.$$

As it is easily seen any solution to (2.8) in $H^2_\sharp$ leads to a solution to System (1.1)-(1.3). Moreover, from any non-negative solution to Equation (2.8) we can obtain an equilibrium to System (1.1)-(1.3) will all the components non-negative in Ω_ℓ. Hence, we can limit ourselves to looking for non-negative solutions $V \in H^2_\sharp$ to Equation (2.8).

Clearly, (2.8) admits the trivial function $V \equiv 0$ as a solution. This solution leads to the equilibrium $\mathbf{X}_u$.

(ii) Let us look for other positive constant solutions to Equation (2.8). We are thus lead to look for solutions to the equation $\Phi(V) - \mu_V V = 0$ which are non-negative.

A straightforward computation reveals that V_i is the unique solution to such an equation. Moreover, for any fixed $r > 0$, V_i is positive if and only if $N > N_{\text{crit}}(r)$ (see (2.4)) i.e., if and only if $(r, N) \in \mathcal{I}$. In this case, replacing $V = V_i$ into (2.7) and (2.2), we immediately conclude that the function $\mathbf{X}_i$ is an equilibrium of System (1.1)-(1.3).

(iii) Showing that $T_u < T_{\max}$ is just an exercise. On the hand, the inequality $T_i < T_{\max}$ in $\mathcal{I}$ follows from the definition of T_i observing that, if $(r, N) \in \mathcal{I}$, then

$$N > N_{\text{crit}} = \frac{\mu_V}{\gamma T_u} > \frac{\mu_V}{\gamma T_{\max}}.$$

(iv) To prove that $\mathbf{X}_u$ and $\mathbf{X}_i$ are the only equilibria of System (1.1)-(1.3) with all the components being non-negative, we adapt to our situation a method due to H.B. Keller [13]. We argue by contradiction. We suppose that $\mathbf{X} = (T, I, V)$ is a solution to System (2.1)-(2.3) with V non-negative in Ω_ℓ and not identically vanishing, and such that $V \not\equiv V_i$. Let us set $W := V - V_i$. Since both V and V_i are solutions to (2.8), clearly $W \in H^2_\sharp$ and solves the equation

$$d_V \Delta W - \mu_V W + \Lambda(V, V_i) W = 0, \tag{2.9}$$

where

$$\begin{aligned}\Lambda(x, y) = &\frac{\gamma N}{2r}\left(r - \mu_T - \gamma x + \sqrt{(r - \mu_T - \gamma x)^2 + \frac{4\alpha r}{T_{\max}}}\right) T_{\max} - \frac{\gamma^2 N T_{\max}}{2r} y \\ &+ \frac{\gamma^2 N T_{\max}}{2r} y \int_0^1 \frac{\gamma(tx + (1-t)y) - r + \mu_T}{\sqrt{[r - \mu_T - \gamma(tx + (1-t)y)]^2 + \frac{4\alpha r}{T_{\max}}}} dt,\end{aligned}$$

for any $x, y \geq 0$.

Let $\lambda_{\max}(V, V_i)$ and $\lambda_{\max}(V, 0)$ denote the maximum eigenvalues in L^2 of the operators $d_V\Delta + \Lambda(V, V_i)Id$ and $d_V\Delta + \Lambda(V, 0)Id$, respectively. By Corollary A.2, we know that

$$\lambda_{\max}(V,0) = -\inf_{\psi\in H^1_\sharp, \psi\not\equiv 0}\left\{\frac{d_V\int_{\Omega_\ell}|\nabla\psi|^2dxdy - \int_{\Omega_\ell}\Lambda(V,0)\psi^2dxdy}{\int_{\Omega_\ell}\psi^2dxdy}\right\},$$

and

$$\lambda_{\max}(V,V_i) = -\inf_{\psi\in H^1_\sharp, \psi\not\equiv 0}\left\{\frac{d_V\int_{\Omega_\ell}|\nabla\psi|^2dxdy - \int_{\Omega_\ell}\Lambda(V,V_i)\psi^2dxdy}{\int_{\Omega_\ell}\psi^2dxdy}\right\}.$$

We now observe that

$$\begin{aligned}\Lambda(V,V_i) - \Lambda(V,0) =& \frac{\gamma^2NT_{\max}}{2r}V_i\left(-1 + \int_0^1 \frac{\gamma(tV+(1-t)V_i) - r + \mu_T}{\sqrt{[r-\mu_T-\gamma(tV+(1-t)V_i)]^2 + \frac{4\alpha r}{T_{\max}}}}dt\right)\\ \le& \frac{\gamma^2NT_{\max}}{2r}V_i\left(-1 + \int_0^1 \frac{|\gamma(tV+(1-t)V_i) - r + \mu_T|}{\sqrt{[r-\mu_T-\gamma(tV+(1-t)V_i)]^2 + \frac{4\alpha r}{T_{\max}}}}dt\right)\\ \le& -\frac{\gamma^2NT_{\max}}{2r}V_i\left(1 - \frac{\gamma(\|V\|_\infty + V_i) + r + \mu_T}{\sqrt{[r+\mu_T+\gamma(\|V\|_\infty+V_i)]^2 + \frac{4\alpha r}{T_{\max}}}}\right) =: -C,\end{aligned}$$

since the function $x \mapsto x(x^2 + 4\alpha r/T_{\max})^{-1/2}$ is increasing in $[0, +\infty)$. Here, we have taken advantage of the Sobolev embedding theorem to infer that $V \in H^2_\sharp$ is continuous in $\overline{\Omega_\ell}$.

Note that the constant C is positive. From this remark we can easily infer that

$$\lambda_{\max}(V, V_i) \le \lambda_{\max}(V, 0) - C.$$

Since W satisfies (2.9) and it does not identically vanish in $\overline{\Omega_\ell}$, $\mu_V \le \lambda_{\max}(V, V_i) < \lambda_{\max}(V, 0)$.

To get to a contradiction, we now rewrite the equation satisfied by V in the following way:

$$d_V\Delta V + \Lambda(V,0)V - \lambda_{\max}(V,0)V = (\mu_V - \lambda_{\max}(V,0))V := Z.$$

Fredholm alternative implies that Z should be orthogonal to the function ψ which spans the eigenspace associated with the eigenvalue $\lambda_{\min}(V, 0)$ of the operator $d_V\Delta + \Lambda(V, 0)Id$. But this can not be the case. Indeed, by Corollary A.2 the function ψ does not change sign in $\overline{\Omega_\ell}$. Moreover, since V is non-negative in Ω_ℓ and it does not identically vanish in Ω_ℓ and, in addition, $\mu_V < \lambda_{\max}(V, 0)$, Z is non-positive and it does not identically vanish in Ω_ℓ. Hence, ψ is not orthogonal to Z. □

3. STABILITY OF THE EQUILIBRIA

In this section we are going to study the stability of the equilibria $\mathbf{X}_u$ and $\mathbf{X}_i$. We begin by studying the stability of the uninfected equilibrium $\mathbf{X}_u$.

Theorem 3.1. *The following properties are satisfied:*

(i) *in the domain* $\mathfrak{U}$ *the uninfected equilibrium* $\mathbf{X}_u$ *is asymptotically stable;*
(ii) *in the domain* $\mathfrak{I}$ *the uninfected equilibrium* $\mathbf{X}_u$ *is unstable.*

Proof. To avoid cumbersome notation, throughout the proof we do not stress explicitly the dependence of the functions and operators on r and N.

We prove the statement showing that the linearized stability principle (see e.g., [11, Chpt. 5, Cor. 5.1.6]) applies to our situation. For this purpose, we begin by observing

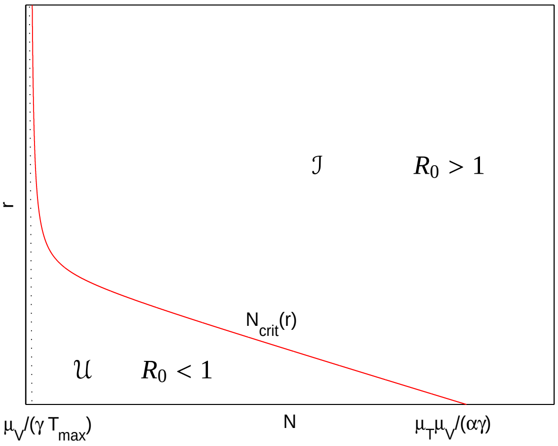

FIGURE 1. Profile of the curve $r \mapsto N_{crit}(r)$ (i.e. $R_0 = 1$) which defines the two domains $\mathcal{U}$ and $\mathcal{I}$. With the values of Table 1, N_{crit} decreases from $\mu_T\mu_V/\alpha\gamma = 666.67$ to $\mu_V/\gamma T_{\max} = 6.67$.

that, for any (N, r) the linearization around $\mathbf{X}_u$ of Problem (1.1)-(1.3) is associated with the linear operator $\mathcal{L}_u$ defined by

$$\mathcal{L}_u = \begin{pmatrix} \left(r - \mu_T - \frac{2rT_u}{T_{\max}}\right) Id & 0 & -\gamma T_u Id \\ 0 & -\mu_I Id & \gamma T_u Id \\ 0 & \mu_I N Id & d_V\Delta - \mu_V Id \end{pmatrix}.$$

Its realization $\boldsymbol{L}_u$ in $(L^2_{\mathbb{C}})^3$ with domain $D(\boldsymbol{L}_u) = L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$ generates an analytic strongly continuous semigroup. Indeed, $\boldsymbol{L}_u$ is a bounded perturbation of the diagonal operator

$$\mathcal{A} = \begin{pmatrix} \left(r - \mu_T - \frac{2rT_u}{T_{\max}}\right) Id & 0 & 0 \\ 0 & -\mu_I Id & 0 \\ 0 & 0 & d_V\Delta - \mu_V Id \end{pmatrix},$$

defined in $L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$, which is clearly sectorial since all its entries are. Hence, we can apply [14, Prop. 2.4.1(i)] and conclude that $\boldsymbol{L}_u$ is sectorial. Since $H^2_{\sharp,\mathbb{C}}$ is dense in $L^2_{\mathbb{C}}$, the associated analytic semigroup is strongly continuous.

To complete the proof, we need to study the spectrum of the operator $\boldsymbol{L}_u$. We fix $\lambda \in \mathbb{C}$ and consider the resolvent equation $\lambda\mathbf{X} - \boldsymbol{L}_u\mathbf{X} = \mathbf{F}$, where $\mathbf{X} = (T, I, V) \in L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$ and $\mathbf{F} = (F_1, F_2, F_3)$ is a given function in $L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times L^2_{\mathbb{C}}$. Writing the previous equation componentwise gives

$$\begin{cases} \left(r - \mu_T - \frac{2rT_u}{T_{\max}}\right) T - \gamma T_u V = \lambda T - F_1, \\ -\mu_I I + \gamma T_u V = \lambda I - F_2, \\ \mu_I N I + d_V \Delta V - \mu_V V = \lambda V - F_3. \end{cases} \tag{3.1}$$

If $\lambda \neq -\mu_I$ we can use the second equation to write I in terms of V. Substituting it in the last equation we get the following self-contained equation for V:

$$d_V\Delta V - \left(\lambda + \mu_V - \frac{\gamma\mu_I N T_u}{\lambda + \mu_I}\right) V = -F_3 - \frac{\mu_I N}{\lambda + \mu_I} F_2. \tag{3.2}$$

We recall that the spectrum of the realization A of the Laplace operator in $L^2_{\mathbb{C}}$, with $H^2_{\sharp,\mathbb{C}}$ as a domain consists of eigenvalues only and it is given by

$$\sigma(A) = \left\{-\frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2) : k_1, k_2 \in \mathbb{N}\right\},$$

(see Appendix A). Hence, if $c(\lambda) := \lambda + \mu_V - \frac{\gamma\mu_I N T_u}{\lambda+\mu_I}$ does not belong to $\sigma(A)$, then Equation (3.2) admits a unique solution $V \in H^2_{\sharp,\mathbb{C}}$. A straightforward computation shows that $c(\lambda)$ is real if and only if λ is real. Moreover, the function $\lambda \mapsto c(\lambda)$ is strictly increasing in $[0, +\infty)$ and $c(0) = \mu_V - \gamma N T_u$ is positive if $(N, r) \in \mathcal{U}$. Hence, if $(N, r) \in \mathcal{U}$, then $c(\lambda) \notin \sigma(A)$ for any λ with non-negative real part, and Equation (3.2) is uniquely solvable.

We can now uniquely determine $I \in L^2_{\mathbb{C}}$ from the second equation in (3.1). Finally, from the first equation in (3.1), observing that

$$r - \mu_T - \frac{2rT_u}{T_{\max}} = -\sqrt{(r-\mu_T)^2 + \frac{4\alpha r}{T_{\max}}} < 0,$$

we can uniquely determine $T \in L^2_{\mathbb{C}}$. We have so proved that any $\lambda \in \mathbb{C}$ with non-negative real part is in the resolvent set of the operator $\boldsymbol{L}_u$, if $(N, r) \in \mathcal{U}$. In view of the linearized stability principle this implies that the trivial uninfected solution to System (1.1)-(1.3) is asymptotically stable.

Let us now suppose that $(N, r) \in \mathcal{I}$ and prove that $\boldsymbol{L}_u$ admits an eigenvalue with positive real part. As above, we are led to consider the function $\lambda \mapsto c(\lambda)$. Now, $c(0) < 0$. Hence, there exists $\lambda_* > 0$ such that $c(\lambda_*) = 0 \in \sigma(A)$. This implies that Problem (3.1), with $F_1 = F_2 = F_3 = 0$ and $\lambda = \lambda_*$, admits a non trivial solution, i.e., $\lambda_* \in \sigma(\boldsymbol{L}_u)$. Again, the linearized stability principle implies that $(T_u, 0, 0)$ is unstable. This completes the proof. □

The issue of the stability of the infected solution is obviously much more complicated. For notational convenience we sort the eigenvalues of the realization A of the Laplacian in $L^2_{\mathbb{C}}$, with $H^2_{\sharp,\mathbb{C}}$ as a domain (see Appendix A), into a non-increasing sequence $\{-\lambda_k\}$. Similarly, we denote by $\tilde{e}_k$ the eigenfunction associated with the eigenvalue λ_k. This allows ut to expand any function $f \in L^2_{\sharp,\mathbb{C}}$ into the Fourier series

$$f = \sum_{k=0}^{+\infty} f_k \tilde{e}_k,$$

where f_k denotes the k-th Fourier coefficient (with respect to the system $(\tilde{e}_k)$) of f. As it is observed in the proof of Theorem A.1, λ_0 is simple and all the other eigenvalues are semisimple, and their multiplicity can be computed explicitly.

We are going to prove the following results.

Theorem 3.2. *Under the hypothesis* (2.6)*, it holds:*

(i) *the infected equilibrium* $\mathbf{X}_i = (T_i, I_i, V_i)$ *is asymptotically stable for* $(N, r) \in \mathcal{I} \setminus \mathcal{P}$*, where* $\mathcal{P}$ *is defined in* (3.17) *with* $k = 0$*;*

(ii) *the infected equilibrium* $\mathbf{X}_i = (T_i, I_i, V_i)$ *is unstable in the interior of* $\mathcal{P}$*.*

3.1. **The resolvent equation.** As in the proof of Theorem 3.1, we do not stress explicitly the dependence on r and N of the operators and the sets that we consider in what follows. For $(N, r) \in \mathcal{I}$, the linearization around $\mathbf{X}_i = (T_i, I_i, V_i)$ of System (1.1)-(1.3) is associated with the linear operator

$$\mathcal{L}_i = \begin{pmatrix} -\left(\frac{\mu_V r}{\gamma N T_{\max}} + \frac{\alpha\gamma N}{\mu_V}\right) Id & 0 & -\frac{\mu_V}{N} Id \\ \left[\frac{\alpha\gamma N}{\mu_V} - \mu_T + r\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)\right] Id & -\mu_I Id & \frac{\mu_V}{N} Id \\ 0 & N\mu_I Id & d_V\Delta - \mu_V Id \end{pmatrix}. \tag{3.3}$$

Proposition 3.3. *For any $(N, r) \in \mathfrak{I}$ the realization $\boldsymbol{L}_i$ of the operator $\mathcal{L}_i$ in $(L^2_{\mathbb{C}})^3$ with domain $D(L_i) = L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$ generates an analytic strongly continuous semigroup. Moreover, the spectrum of $\boldsymbol{L}_i$ is given by*

$$\sigma(\boldsymbol{L}_i) = \left\{ -\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}, -\mu_I \right\} \cup \bigcup_{k\in\mathbb{N}} \sigma_k, \tag{3.4}$$

where, for any $k \in \mathbb{N}$, σ_k is the spectrum of the matrix

$$M_k = \begin{pmatrix} -\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V} & 0 & -\frac{\mu_V}{N} \\ \frac{\alpha\gamma N}{\mu_V} - \mu_T + r\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right) & -\mu_I & \frac{\mu_V}{N} \\ 0 & N\mu_I & -d_V\lambda_k - \mu_V \end{pmatrix}.$$

Proof. The same arguments as in the proof of Theorem 3.1 show that $\boldsymbol{L}_i$ generates an analytic strongly continuous semigroup in $(L^2_{\mathbb{C}})^3$.

Let us determine its spectrum. For this purpose we use the discrete Fourier transform. If a function $\mathbf{v} = (v_1, v_2, v_3)$ in $L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$ solves the resolvent equation $\lambda\mathbf{v} - \boldsymbol{L}_i\mathbf{v} = \mathbf{f}$, for some $\lambda \in \mathbb{C}$ and $\mathbf{f} = (f_1, f_2, f_3)$ in $(L^2_{\mathbb{C}})^3$, then its Fourier coefficients $\mathbf{v}_k = (v_{1,k}, v_{2,k}, v_{3,k})$ $(k = 0, 1, \ldots)$ solve the infinitely many equations $(\lambda Id - M_k)\mathbf{v}_k = \mathbf{f}_k$ $(k = 0, 1, \ldots)$, where $\mathbf{f}_k = (f_{1,k}, f_{2,k}, f_{3,k})$ and $f_{j,k}$ denotes the k-th Fourier coefficient of the function f_j $(j = 1, 2, 3)$. Clearly, any eigenvalue of M_k $(k = 0, 1, \ldots)$ is an eigenvalue of $\boldsymbol{L}_i$. Therefore, $\sigma(\boldsymbol{L}_i) \supset \bigcup_{k\in\mathbb{N}} \sigma_k$.

On the other hand, if $\lambda \notin \sigma_k$ for any $k = 0, 1, \ldots$, then all the coefficients $(v_{1,k}, v_{2,k}, v_{3,k})$ are uniquely determined through the formulae

$$v_{1,k} = \frac{1}{\mathcal{D}_k(\lambda)} \left\{ [(\lambda + \mu_I)(\lambda + d_V\lambda_k + \mu_V) - \mu_I\mu_V] f_{1,k} - \mu_I\mu_V f_{2,k} - \frac{\mu_V}{N}(\lambda + \mu_I) f_{3,k} \right\}, \tag{3.5}$$

$$\begin{aligned} v_{2,k} = & \frac{1}{\mathcal{D}_k(\lambda)} \left\{ \frac{\lambda + d_V\lambda_k + \mu_V}{\gamma\mu_V N T_{\max}} [(-\mu_V^2 r + \alpha\gamma^2 N^2 T_{\max} - \gamma\mu_T\mu_V N T_{\max} + \gamma\mu_V r N T_{\max}) f_{1,k} \right. \\ & \qquad + (\lambda\gamma\mu_V N T_{\max} + \mu_V^2 r + \alpha\gamma^2 N^2 T_{\max}) f_{2,k}] \\ & \left. + \frac{\mu_V}{\gamma N^2 T_{\max}} (2\mu_V r - \gamma r N T_{\max} + \gamma\mu_T N T_{\max} + \lambda\gamma N T_{\max}) f_{3,k} \right\}, \end{aligned} \tag{3.6}$$

$$\begin{aligned} v_{3,k} = & \frac{1}{\mathcal{D}_k(\lambda)} \left\{ \frac{\mu_I}{\gamma\mu_V T_{\max}} [(\alpha\gamma^2 N^2 T_{\max} - \gamma\mu_T\mu_V N T_{\max} + \gamma\mu_V r N T_{\max} - \mu_V^2 r) f_{1,k} \right. \\ & \qquad + (\lambda\gamma\mu_V N T_{\max} + \mu_V^2 r + \alpha\gamma^2 N^2 T_{\max}) f_{2,k}] \\ & \left. + \frac{\lambda + \mu_I}{\gamma\mu_V N T_{\max}} (\lambda\gamma\mu_V N T_{\max} + \mu_V^2 r + \alpha\gamma^2 N^2 T_{\max}) f_{3,k} \right\}, \end{aligned} \tag{3.7}$$

where

$$\mathcal{D}_k(\lambda) = \lambda^3 + d_{1,k}\lambda^2 + d_{2,k}\lambda + d_{3,k}, \qquad k = 0, 1, \ldots, \tag{3.8}$$

and

$$d_{1,k} = d_{1,k}(N, r) = d_V\lambda_k + \mu_I + \mu_V + \frac{\mu_V r}{\gamma N T_{\max}} + \frac{\alpha\gamma N}{\mu_V}, \tag{3.9}$$

$$d_{2,k} = d_{2,k}(N, r) = \mu_I d_V\lambda_k + \alpha\gamma N + \frac{\alpha\gamma N}{\mu_V}(\mu_I + d_V\lambda_k) + \frac{\mu_V r}{\gamma N T_{\max}}(\mu_I + \mu_V + d_V\lambda_k), \tag{3.10}$$

$$d_{3,k} = d_{3,k}(N, r) = \mu_I\mu_V(r - \mu_T) + \frac{\alpha\gamma\mu_I N}{\mu_V}(\mu_V + d_V\lambda_k) + \frac{\mu_I\mu_V r}{\gamma N T_{\max}}(d_V\lambda_k - \mu_V). \tag{3.11}$$

Note that, if λ differs from both $-\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}$ and $-\mu_I$, then

$$\mathcal{D}_k(\lambda) \sim d_V \left\{ \lambda^2 + \lambda\left(\mu_I + \frac{\alpha\gamma N}{\mu_V} + \frac{\mu_V r}{\gamma N T_{\max}}\right) + \frac{\alpha\gamma\mu_I N}{\mu_V} + \frac{\mu_I\mu_V r}{\gamma N T_{\max}} \right\} \lambda_k,$$

as $k \to +\infty$. Hence, for any $\lambda \notin \left\{-\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}, -\mu_I\right\} \cup \bigcup_{k\in\mathbb{N}} \sigma_k$, it holds that

$$
\begin{aligned}
v_{1,k} &\sim \frac{\lambda+\mu_I}{\lambda^2+\lambda\left(\mu_I+\frac{\alpha\gamma N}{\mu_V}+\frac{\mu_V r}{\gamma N T_{\max}}\right)+\frac{\alpha\gamma\mu_I N}{\mu_V}+\frac{\mu_I\mu_V r}{\gamma N T_{\max}}}\, f_{1,k},\\
v_{2,k} &\sim \frac{\left(-\frac{\mu_V r}{\gamma N T_{\max}}+\frac{\alpha\gamma N}{\mu_V}+r-\mu_T\right) f_{1,k}+\left(\frac{\mu_V r}{\gamma N T_{\max}}+\frac{\alpha\gamma N}{\mu_V}+\lambda\right) f_{2,k}}{\lambda^2+\lambda\left(\mu_I+\frac{\alpha\gamma N}{\mu_V}+\frac{\mu_V r}{\gamma N T_{\max}}\right)+\frac{\alpha\gamma\mu_I N}{\mu_V}+\frac{\mu_V\mu_I r}{\gamma N T_{\max}}},\\
v_{3,k} &\sim \frac{1}{d_V\lambda_k\left\{\lambda^2+\lambda(\mu_I+\frac{\alpha\gamma N}{\mu_V}+\frac{\mu_V r}{\gamma N T_{\max}})+\frac{\alpha\gamma\mu_I N}{\mu_V}+\frac{\mu_I\mu_V r}{\gamma N T_{\max}}\right\}}\\
&\qquad\times\left\{\left(\frac{\alpha\gamma\mu_I N^2}{\mu_V}-\frac{\mu_I\mu_V r}{\gamma T_{\max}}+\mu_I r N-\mu_I\mu_T N\right)f_{1,k}+\left(\frac{\alpha\gamma\mu_I N^2}{\mu_V}+\frac{\mu_I\mu_V r}{\gamma T_{\max}}+\lambda\mu_I N\right)f_{2,k}\right.\\
&\qquad\qquad\left.+(\lambda+\mu_I)\left(\lambda+\frac{\alpha\gamma N}{\mu_V}+\frac{\mu_V r}{\gamma N T_{\max}}\right)f_{3,k}\right\},
\end{aligned}
$$

as $k \to +\infty$. Thus, the sequences $\{v_{1,k}\}$, $\{v_{2,k}\}$ and $\{\lambda_k v_{3,k}\}$ are square-summable. This shows that the series whose Fourier coefficients are $v_{1,k}$, $v_{2,k}$ and $v_{3,k}$, respectively, converge in $L^2_{\mathbb{C}}$ (the first two ones) and in $H^2_{\sharp,\mathbb{C}}$ (the latter one). The inclusion $\sigma \subset \left\{-\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}, -\mu_I\right\} \cup \bigcup_{k\in\mathbb{N}} \sigma_k$ follows. On the other hand, the previous computations show that, if $\lambda = -\mu_I$ or $\lambda = -\frac{\mu_V r}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}$, then the series having $v_{1,k}$, $v_{2,k}$ and $v_{3,k}$ as Fourier coefficients do not, in general, converge in L^2 (the first two ones) and in $H^2_\sharp$ (the latter one). Hence, these values of λ belong to the essential spectrum of $\boldsymbol{L}_i$. Thus, (3.3) is proved. □

3.2. **Study of σ_k.** Clearly, at fixed $k = 0, 1, \ldots$, each set σ_k consists of at most three eigenvalues $\nu_{j,k}$, $j = 1, 2, 3$, either all real, or one real and two complex conjugates, which verify the equation $\lambda^3 + d_{1,k}\lambda^2 + d_{2,k}\lambda + d_{3,k} = 0$, with $d_{j,k}$ ($j = 1, 2, 3$) being given by (3.9)-(3.11).

The Routh-Hurwitz criterion enables us to determine whether the elements of σ_k have negative real parts. The latter holds if and only if $d_{1,k}$, $d_{3,k}$ and the leading Hurwitz determinant $D_{2,k} = d_{1,k}d_{2,k} - d_{3,k}$ are positive. The case $k = 0$ corresponds to the system of ODEs considered in [6].

Obviously, $d_{1,k} > 0$. As far as $d_{3,k}$ is concerned, we remark that $d_{3,k}(N, r) > d_{3,0}(N, r)$, which is positive in $\mathcal{I}$ and vanishes at $N_{\text{crit}}(r)$.

For $(N, r) \in \mathcal{I}$, we compute the Hurwitz determinant $D_{2,k}(N, r)$ and we get

$$
D_{2,k}(N,r) = \frac{1}{\gamma^2\mu_V^2 N^2 T_{\max}^2}\left(A_k r^2 + B_k(N) r + C_k(N)\right), \tag{3.12}
$$

where

$$
\begin{aligned}
A_k &= \mu_V^4(\mu_I+\mu_V+d_V\lambda_k),\\
B_k(N) &= \gamma\mu_V^2 N T_{\max}\Big[\mu_V d_V^2\lambda_k^2+2\alpha\gamma d_V N\lambda_k+2\mu_V^2 d_V\lambda_k+2\mu_I\mu_V d_V\lambda_k\\
&\qquad\qquad -\gamma\mu_I\mu_V N T_{\max}+2\alpha\gamma\mu_I N+2\alpha\gamma\mu_V N+\mu_I^2\mu_V+3\mu_I\mu_V^2+\mu_V^3\Big],\\
C_k(N) &= N^2\gamma^2 T_{\max}^2\Big(\mu_I\mu_V^2 d_V^2\lambda_k^2+\alpha\gamma\mu_V d_V^2 N\lambda_k^2+\alpha^2\gamma^2 d_V N^2\lambda_k+2\alpha\gamma\mu_V^2 d_V N\lambda_k\\
&\qquad\qquad +\mu_I\mu_V^3 d_V\lambda_k+\mu_I^2\mu_V^2 d_V\lambda_k+2\alpha\gamma\mu_I\mu_V d_V N\lambda_k+\alpha\gamma\mu_V^3 N+\alpha\gamma\mu_I\mu_V^2 N\\
&\qquad\qquad +\alpha\gamma\mu_I^2\mu_V N+\alpha^2\gamma^2\mu_V N^2+\alpha^2\gamma^2\mu_I N^2+\mu_I\mu_T\mu_V^3\Big).
\end{aligned}
$$

Both A_k and $C_k(N)$ are positive, whereas $B_k(N)$ vanishes at

$$
N_{0,k} = -\frac{\mu_V(d_V^2\lambda_k^2+2(\mu_I+\mu_V)d_V\lambda_k+3\mu_I\mu_V+\mu_I^2+\mu_V^2)}{\gamma(2\alpha d_V\lambda_k+2\alpha\mu_I+2\alpha\mu_V-\mu_I\mu_V T_{\max})}. \tag{3.13}
$$

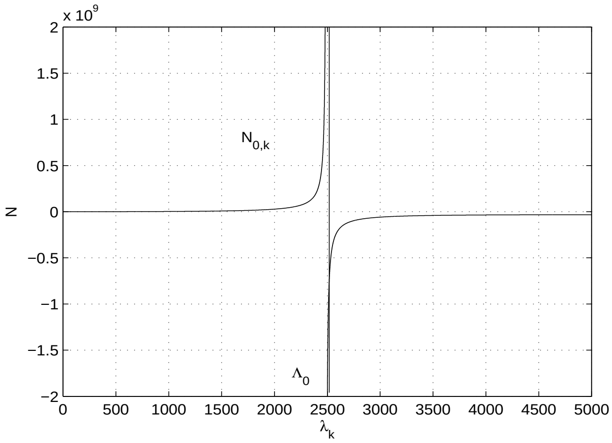

FIGURE 2. Profile of the curve $N_{0,k}$.

In (3.13), as a function of λ_k, the denominator vanishes at

$$\Lambda_0 = \frac{\mu_I \mu_V T_{\max}}{2\alpha d_V} - \frac{\mu_I + \mu_V}{d_V},$$

which is positive and generically does not meet any of the λ_k's, $k \geq 1$. There are two cases (see Fig. 2):

(i) $0 \leq \lambda_k < \Lambda_0$, hence $N_{0,k} > 0$. Then, $B_k(N) > 0$ if $0 < N < N_{0,k}$;
(ii) $\lambda_k > \Lambda_0$, hence $N_{0,k} < 0$ and in this case $B_k(N)$ is positive for any $N > 0$.

The sign of the polynomial $A_k r^2 + B_k(N) r + C_k(N)$ is obviously related to the discriminant

$$\Delta_k(N) = (B_k(N))^2 - 4A_k C_k(N) = \gamma^2 \mu_V^5 N^2 T_{\max}^2 (a_k N^2 + b_k N + c_k),$$

which in turn is of the sign of $a_k N^2 + b_k N + c_k$. The coefficients a_k, b_k and c_k read:

$$\begin{aligned}
a_k =& \gamma^2 \mu_I T_{\max} \Big\{ \mu_I \mu_V T_{\max} - 4\alpha d_V \lambda_k - 4\alpha(\mu_I + \mu_V) \Big\}, \\
b_k =& -2\gamma \mu_I \mu_V \Big\{ [d_V^2 \lambda_k^2 + 2(\mu_I + \mu_V) d_V \lambda_k + \mu_I^2 + 3\mu_I \mu_V + \mu_V^2] T_{\max} - 4\alpha d_V \lambda_k - 4\alpha(\mu_I + \mu_V) \Big\}, \\
c_k =& \mu_V \Big\{ (d_V^2 \lambda_k^2 - \mu_I^2)^2 + 4\mu_V d_V^3 \lambda_k^3 + 6\mu_V(\mu_I + \mu_V) d_V^2 \lambda_k^2 \\
& \quad + 4\mu_V [\mu_V^2 + 3\mu_I \mu_V + \mu_I(2\mu_I - \mu_T)] d_V \lambda_k \\
& \quad + 2\mu_I^2 \mu_V (3\mu_I - 2\mu_T) + 6\mu_I \mu_V^3 + \mu_I \mu_V^2 (11\mu_I - 4\mu_T) + \mu_V^4 \Big\}.
\end{aligned}$$

Let us examine the signs of these coefficients.

(i) As a function of λ_k, the coefficient a_k vanishes at

$$\Lambda_2 = \frac{\mu_I \mu_V T_{\max}}{4\alpha d_V} - \frac{\mu_I + \mu_V}{d_V} = \Lambda_0 - \frac{\mu_I \mu_V T_{\max}}{4\alpha d_V}.$$

Clearly, Λ_2 is positive thanks to (2.6) and, as Λ_0, generically does not meet any of the λ_k's for $k \geq 0$. Then, a_k is positive if $0 \leq \lambda_k < \Lambda_2$ and negative otherwise.
(ii) $b_k < 0$ due the hypothesis (2.6).
(iii) $c_k > 0$ under the biologically relevant hypothesis $\mu_I > \mu_T$ (see (2.5)).

Next we compute:

$$\begin{aligned}
\delta_k :=& b_k^2 - 4a_k c_k \\
=& 16\gamma^2 \mu_I \mu_V (\mu_I + \mu_V + d_V \lambda_k) \\
& \times \Big\{ \alpha(d_V^2 \lambda_k^2 - \mu_I^2)^2 T_{\max} + 4\alpha \mu_V d_V^3 T_{\max} \lambda_k^3 + (\mu_I^2 \mu_V T_{\max} + 6\alpha \mu_V^2 + 4\alpha \mu_I \mu_V) d_V^2 T_{\max} \lambda_k^2
\end{aligned}$$

$$
\begin{aligned}
&+\mu_V[\mu_I^2(\mu_I+\mu_V)T_{\max}^2+4\alpha(\mu_I^2+2\mu_I\mu_V+\mu_V^2-\mu_I\mu_T)T_{\max}+4\alpha^2\mu_I]d_V\lambda_k\\
&+\mu_I^2\mu_T\mu_V^2T_{\max}^2+\alpha[\mu_I^4+4\mu_I\mu_V^3+\mu_V^4+4\mu_I^2\mu_V(\mu_I-\mu_T)+\mu_I\mu_V^2(5\mu_I-4\mu_T)]T_{\max}\\
&+4\alpha^2\mu_I^2\mu_V+4\alpha^2\mu_I\mu_V^2\Big\}.
\end{aligned}
$$

Again, thanks to the hypothesis $\mu_I > \mu_T$, δ_k is always positive. Therefore, the roots of $a_kN^2 + b_kN + c_k = 0$, namely the ones of $\Delta_k(N) = 0$, are:

$$
N_{1,k} = \frac{-b_k - \sqrt{\delta_k}}{2a_k}, \qquad N_{2,k} = \frac{-b_k + \sqrt{\delta_k}}{2a_k}. \tag{3.14}
$$

Remark 3.4. *Since $B_k(N_{0,k}) = 0$ and $A_k(N_{0,k})$, $C_k(N_{0,k})$ are both positive, $a_k(N_{0,k}))^2 + b_kN_{0,k} + c_k < 0$. This provides us with a useful information regarding the position of $N_{0,k}$ with respect to $N_{1,k}$ and $N_{2,k}$, according to* (3.14)*, i.e., $N_{1,k} < N_{0,k} < N_{2,k}$ if $a_k > 0$ and $N_{0,k} < N_{2,k}$ or $N_{0,k} > N_{1,k}$ if $a_k < 0$. In particular, $N_{0,k}$ can meet neither $N_{1,k}$ nor $N_{2,k}$.*

Now we are in a position to begin the discussion, depending on the position of λ_k. Let us distinguish three cases.

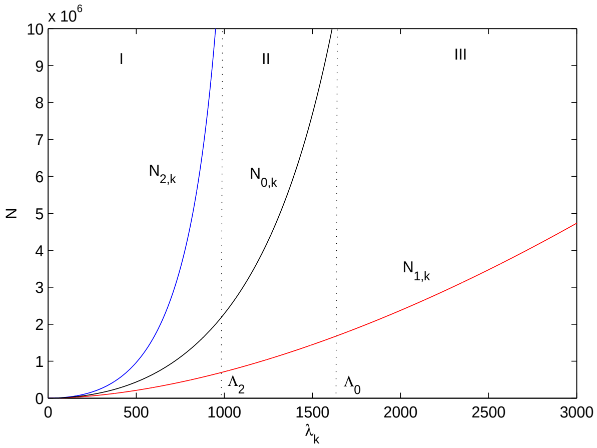

FIGURE 3. Comparison of the three curves $N_{0,k}$, $N_{1,k}$ and $N_{2,k}$, as functions of λ_k.

Case I: $0 \le \lambda_k < \Lambda_2$. In this situation $a_k > 0$, $b_k < 0$ and $c_k > 0$ and k ranges in a finite set of indexes. It is an extension of the case $k = 0$, see [6]. It follows from Remark 3.4 that B_k vanishes between $N_{1,k}$ and $N_{2,k}$ which are both positive. In particular, for $T_{\max}$ large enough (as we are assuming), $N_{1,k} > \mu_V/(\gamma T_{\max})$. Indeed,

$$
\begin{aligned}
&a_k\left(\frac{\mu_V}{\gamma T_{\max}}\right)^2 + b_k\frac{\mu_V}{\gamma T_{\max}} + c_k\\
=&\mu_V(d_V^2\lambda_k^2-\mu_I^2)^2+4\mu_V^2d_V^3\lambda_k^3+4\mu_I\mu_V^2d_V^2\lambda_k^2+6\mu_V^3d_V^2\lambda_k^2+8\mu_I\mu_V^3d_V\lambda_k\\
&+4\mu_I\mu_V^2(\mu_I-\mu_T)d_V\lambda_k+4\mu_V^4d_V\lambda_k+2\mu_I^3\mu_V^2+2\mu_I^2\mu_V^3+2\mu_I^2\mu_V^2(\mu_I-\mu_T)\\
&+4\mu_I\mu_V^4+4\mu_I\mu_V^3(\mu_I-\mu_T)+\mu_V^5+o(1),
\end{aligned}
$$

as $T_{\max} \to +\infty$. Again, since $\mu_I > \mu_T$,

$$
a_k\left(\frac{\mu_V}{\gamma T_{\max}}\right)^2 + b_k\frac{\mu_V}{\gamma T_{\max}} + c_k > 0,
$$

if $T_{\max}$ is large enough. It follows that either $\mu_V/(\gamma T_{\max}) < N_{1,k}$ or $\mu_V/(\gamma T_{\max}) > N_{2,k}$. But as it is immediately seen, $N_{2,k} > \mu_V/(\gamma T_{\max})$. Indeed,

$$
N_{2,k} \sim \frac{d_V^2\lambda_k^2 + 2(\mu_I+\mu_V)d_V\lambda_k + \mu_I^2 + 3\mu_I\mu_V + \mu_V^2}{\gamma\mu_I T_{\max}}
$$

$$
\begin{aligned}
&+\frac{\sqrt{\mu_V d_V^2\lambda_k^2 + +(\mu_V^2+\mu_I\mu_V)d_V\lambda_k + \mu_T\mu_V^2}}{2\gamma^2\mu_I\mu_V T_{\max}}\\
&\ge \frac{3\mu_V}{\gamma T_{\max}},
\end{aligned}
$$

as $T_{\max} \to +\infty$. Hence, $\mu_V/(\gamma T_{\max}) < N_{1,k}$ as it has been claimed.

We consider four subcases depending on the position of N with respect to $N_{1,k}$ and $N_{2,k}$.

(i) Assume $N_{1,k} < N < N_{2,k}$. Then, $\Delta_k(N) < 0$. Since $A_k > 0$, it follows that $D_{2,k}(N,r) > 0$ for all $r > r_{\text{crit}}(N)$ (see (3.12) and recall that we are taking (N,r) from $\mathcal{I}$).

(ii) If $N < N_{1,k}$, then $B_k(N) > 0$. Hence, $A_k r^2 + B_k(N)r + C_k(N) > 0$ for any $r \ge 0$ since $A_k, B_k, C_k > 0$. It thus follows that $D_{2,k}(N,r) > 0$ for all $r > r_{\text{crit}}(N)$.

(iii) If $N > N_{2,k}$, then $B_k(N) < 0$. Since $\Delta_k(N) > 0$, the equation $A_k r^2 + B_k(N)r + C_k(N) = 0$ admits the two real and positive roots:

$$
r_{1,k}(N) = \frac{-B_k(N) - \sqrt{\Delta_k(N)}}{2A_k}, \qquad r_{2,k}(N) = \frac{-B_k(N) + \sqrt{\Delta_k(N)}}{2A_k}. \tag{3.15}
$$

Observe that

$$
\begin{aligned}
r_{1,k}(N) =&\frac{2C_k}{-B_k + \sqrt{\Delta_k}}\\
\sim&\frac{1}{\mu_I\mu_V^3}\Big(\mu_I\mu_T\mu_V^3 + \alpha\gamma\mu_V^3 N + \alpha\gamma\mu_I\mu_V^2 N + \alpha\gamma\mu_I^2\mu_V N + \alpha^2\gamma^2\mu_V N^2\\
&\qquad + \alpha^2\gamma^2\mu_I N^2 + \alpha^2\gamma^2 d_V N^2\lambda_k + 2\alpha\gamma\mu_V^2 d_V N\lambda_k + \mu_I\mu_V^3 d_V\lambda_k\\
&\qquad + \mu_I\mu_V^2 d_V^2\lambda_k^2 + \alpha\gamma\mu_V d_V^2 N\lambda_k^2 + \mu_I^2\mu_V^2 d_V\lambda_k + 2\alpha\gamma\mu_I\mu_V d_V N\lambda_k\Big)\\
&> \mu_T > \frac{(\mu_T\mu_V - \alpha\gamma N)^+}{\mu_V} = r_{\text{crit}}(N),
\end{aligned} \tag{3.16}
$$

as $T_{\max} \to +\infty$. Consequently, the Hurwitz determinant $D_{2,k}(N,r)$ is positive for $r_{\text{crit}}(N) \le r < r_{1,k}(N)$ and $r > r_{2,k}(N)$, it vanishes at $r = r_{1,k}(N)$ and $r = r_{2,k}(N)$, and is negative for $r_{1,k}(N) < r < r_{2,k}(N)$.

(iv) Assume $N \in \{N_{1,k}, N_{2,k}\}$. In such a case, $\Delta_k(N_{j,k}) = 0$ and the polynomial $A_k r^2 + B_k(N_{j,k})r + C_k(N_{j,k})$ has the double root $r_k(N_{j,k}) = -B_k(N_{j,k})/2A_k$. However, this solution makes sense only if $B_k(N_{j,k}) < 0$. Hence, only the case $N = N_{2,k}$ is relevant, and we have $D_{2,k}(N_{2,k}, r) > 0$ for $r > r_{\text{crit}}(N_{2,k})$ except at $r(N_{2,k}) = -B_k(N_{2,k})/2A_k$, where it vanishes.

We are now in a position to define the subdomain $\mathcal{P}_k$ of $\mathcal{I}$ by

$$
\mathcal{P}_k = \{(N,r) : N \ge N_{2,k},\ r_{1,k}(N) \le r \le r_{2,k}(N)\}, \tag{3.17}
$$

see (3.14) and (3.15), and at $N = N_{2,k}$, $r_{1,k}(N_{2,k}) = r_{2,k}(N_{2,k}) = -B_k(N_{2,k})/2A_k$. In the domain $\mathcal{I}$, $d_{1,k}$ and $d_{3,k}$ are positive, and $D_{2,k}(N,r)$ is positive except in $\mathcal{P}_k$. More precisely, the Hurwitz determinant $D_{2,k}(N,r)$ is negative in the interior of $\mathcal{P}_k$ and it vanishes on the boundary of $\mathcal{P}_k$.

Case II: $\boldsymbol{\Lambda_2 < \lambda_k < \Lambda_0}$. Now, $a_k < 0$, $b_k < 0, c_k > 0$. Hence, $N_{2,k} < 0, N_{1,k} > 0$. Since $N_{0,k} > 0$, it holds that $N_{0,k} > N_{1,k}$ according to Remark 3.4. Moreover, as it is immediately seen, $N_{0,k} > (\gamma T_{\max})^{-1}\mu_V$. There are two possibilities:

(i) $(N,r) \in \mathcal{I}$ satisfies $N < N_{0,k}$. Then, $B_k(N) > 0$. Therefore, $A_k r^2 + B_k(N)r + C_k(N) > 0$ for any $r \ge r_{\text{crit}}(N)$ since the coefficients are all positive. It thus follows that $D_{2,k}(N,r) > 0$.

(ii) $(N,r) \in \mathcal{I}$ satisfies $N \ge N_{0,k}$. Then, $N > N_{1,k}$ and $a_k N^2 + b_k N + c_k < 0$. Therefore $\Delta_k(N) < 0$ and $A_k r^2 + B_k(N)r + C_k(N)$ has the sign of A_k which is positive, so $D_{2,k}(N,r) > 0$.

Case III: $\lambda_k > \Lambda_0$. Here, $N_{0,k} < 0$ and, therefore, $B_k(N) > 0$ for all $N > 0$. The conclusion is the same as in Case II (i).

We summarize our results in the following proposition.

Proposition 3.5. *Denote by K_2 the largest integer such that $\lambda_{K_2} < \Lambda_2$. Then,*

(i) *for $k = 0, \dots, K_2$, the Hurwitz determinant $D_{2,k}(N, r)$ is, respectively, negative in the interior of the subdomain $\mathcal{P}_k$ of $\mathcal{I}$, positive in $\mathcal{I} \setminus \mathcal{P}_k$, and it vanishes on the boundary of $\mathcal{P}_k$;*
(ii) *for $k = K_2 + 1, K_2 + 2, \dots$, the Hurwitz determinant $D_{2,k}(N, r)$ is always positive in $\mathcal{I}$.*

Remark 3.6. *To give an idea, with the numerical values of Table 1 and $\ell = 1$, $\Lambda_2 = 1239.5$ and lies between $\lambda_{97} = 116\pi^2$ and $\lambda_{98} = 128\pi^2$, therefore $K_2 = 97$.*

To conclude this subsection we prove the following proposition which gives a much clearer picture of how the sets $\mathcal{P}_k$ are ordered in the space of the parameters.

Proposition 3.7. *Let K_2 be as in the statement of Proposition 3.5. Then, the following set inclusions hold:*

$$\mathcal{P}_{K_2} \subseteq \mathcal{P}_{K_2-1} \subseteq \cdots \subseteq \mathcal{P}_k \subseteq \cdots \subseteq \mathcal{P}_1 \subsetneq \mathcal{P}_0.$$

Proof. To begin with we claim that $N_{2,k} < N_{2,k+1}$ (see (3.14)) for any $k = 0, \dots, K_2 - 1$. To prove the claim we observe that $\delta_k = \delta(\lambda_k)$, where

$$\begin{aligned}
\delta(x) =&16\gamma^2\mu_I\mu_V(\mu_I + \mu_V + d_V x)\\
&\times\Big\{\alpha d_V^4 T_{\max}x^4 + 4\alpha\mu_V d_V^3 T_{\max}x^3 + (\mu_I^2\mu_V T_{\max} + 6\alpha\mu_V^2 - 2\alpha\mu_I^2 + 4\alpha\mu_I\mu_V)d_V^2 T_{\max}x^2\\
&\quad + \mu_V[\mu_I^2(\mu_I + \mu_V)T_{\max}^2 + 4\alpha(\mu_I^2 + 2\mu_I\mu_V + \mu_V^2 - \mu_I\mu_T)T_{\max} + 4\alpha^2\mu_I]d_V x\\
&\quad + \mu_I^2\mu_T\mu_V^2 T_{\max}^2 + \alpha[\mu_I^4 + 4\mu_I\mu_V^3 + \mu_V^4 + 4\mu_I^2\mu_V(\mu_I - \mu_T) + \mu_I\mu_V^2(5\mu_I - 4\mu_T)]T_{\max}\\
&\quad + 4\alpha^2\mu_I^2\mu_V + 4\alpha^2\mu_I\mu_V^2\Big\}.
\end{aligned}$$

We compute the derivative of the function δ and get

$$\begin{aligned}
\delta'(x) = 16\gamma^2\mu_I\mu_V\Big\{&5\alpha d_V^4 T_{\max}x^4 + 4\alpha(\mu_I + 5\mu_V)d_V^3 T_{\max}x^3\\
&+ 3(\mu_I^2\mu_V T_{\max} + 8\alpha\mu_I\mu_V - 2\alpha\mu_I^2 + 10\alpha\mu_V^2)d_V^2 T_{\max}x^2\\
&+ 4[\mu_I^2\mu_V(\mu_I + \mu_V)T_{\max}^2\\
&\qquad + \alpha(9\mu_I\mu_V^2 + 3\mu_I^2\mu_V - 2\mu_I\mu_T\mu_V - \mu_I^3 + 5\mu_V^3)T_{\max} + 2\alpha^2\mu_I\mu_V]d_V x\\
&+ \mu_I^2\mu_V(\mu_T\mu_V + \mu_V^2 + \mu_I^2 + 2\mu_I\mu_V)T_{\max}^2\\
&+ \alpha(17\mu_I^2\mu_V^2 - 8\mu_I\mu_T\mu_V^2 + 8\mu_I^3\mu_V + 16\mu_I\mu_V^3 + 5\mu_V^4 + \mu_I^4 - 8\mu_I^2\mu_T\mu_V)T_{\max}\\
&+ 8\alpha^2\mu_I^2\mu_V + 8\alpha^2\mu_I\mu_V^2\Big\}d_V.
\end{aligned}$$

Under hypothesis (2.6) this function is positive and, consequently, $k \mapsto \delta_k$ is non-decreasing.

Similarly, $a_k = a(\lambda_k)$ and $b_k = b(\lambda_k)$, the functions a and b being strictly decreasing. Hence, the sequences $\{a_k\}$ and $\{b_k\}$ are non-increasing. Since $a_k > 0$ and $b_k < 0$ we now easily get the claim.

To complete the proof of the inclusion $\mathcal{P}_{k+1} \subseteq \mathcal{P}_k$ for any $k = 0, \dots, K_2-1$, we show that, for any $N \geq N_{2,k+1}$ we have $r_{1,k}(N) \leq r_{1,k+1}(N) < r_{2,k+1}(N) \leq r_{2,k}(N)$. These properties follow immediately from the definitions of $r_{1,k}(N)$ and $r_{2,k}(N)$ observing that $0 \leq A_j \leq A_{j+1}$, $B_j(N) \leq B_{j+1}(N) \leq 0$ (since $N \geq N_{0,h}$ for any $h = 0, \dots, k + 1$; recall that we are in the Case I(iii) where $N_{1,k}$ and $N_{2,k}$ are both positive, and take Remark 3.4 into account) and $0 \leq C_j \leq C_{j+1}$ for any $j = 0, \dots, K_2 - 1$.

Finally, since $\lambda_0 < \lambda_1$, $N_{2,1} > N_{2,0}$. Consequently, $\mathcal{P}_1$ is properly contained in $\mathcal{P}_0$. □

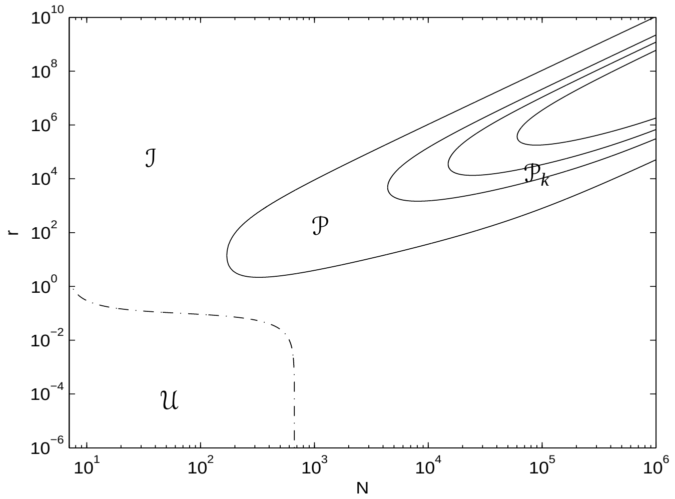

Figure 4. The sets $\mathcal{P}_k$.

3.3. **Proof of Theorem 3.2.** The proof follows from Propositions 3.5, 3.7, Routh-Hurwitz criterion and the linearized stability principle.

(i) As Proposition 3.5 shows, for $k = 0, \dots, K_2$ the leading Hurwitz determinants $D_{2,k}(N, r)$ (see (3.12)) are positive in $\mathcal{I} \setminus \mathcal{P}_k$. On the other hand, if $k \geq K_2 + 1$, then $D_{2,k}(N, r) > 0$ for any $(N, r) \in \mathcal{I}$.

By Proposition 3.7 it holds that $\mathcal{P}_k \subsetneq \mathcal{P}_0$, $k = 1, 2, \dots$. Hence, we conclude that $D_{2,k}(N, r) > 0$ for any $k \in \mathbb{N}$, if $(N, r) \in \mathcal{I} \setminus \mathcal{P}_0$. Since the other two Hurwitz determinants are positive in the whole of $\mathcal{I}$, it follows from the Ruth-Hurwitz criterion that, if $(N, r) \in \mathcal{I} \setminus \mathcal{P}$, then all the element of $\bigcup_{k\in\mathbb{N}} \sigma_k$ have negative real part. Hence, $\operatorname{Re}\sigma(\boldsymbol{L}_i) < 0$ (see (3.4)). It remains to invoke the linearized stability principle as in the proof of Theorem 3.1.

(ii) The instability of $\mathbf{X}_u$ can be deduced from [6] which deals with System (1.1)-(1.3) in the case when $d_V = 0$ and shows that, in this situation, the infected equilibrium $\mathbf{X}_i$ is unstable. □

4. HOPF BIFURCATION AND INSTABILITY

For fixed $N > 0$ we take the logistic parameter $r > r_{\text{crit}}(N)$ as a bifurcation parameter.

We recall that at fixed $(N, r) \in \mathcal{I}$, System (1.1)-(1.3) has two equilibria: the uninfected trivial solution $\mathbf{X}_u(N, r)$ and the infected, positive solution $\mathbf{X}_i(N, r)$. At $\mathbf{X}_i(N, r)$, the Jacobian matrix is $\mathcal{L}_i = \mathcal{L}_{i,N,r}$, see (3.3). As we already observed in Proposition 3.3, the realization $\boldsymbol{L}_{i,N,r}$ of the operator $\mathcal{L}_{i,N,r}$ in $(L^2_{\mathbb{C}})^3$ with domain $D(\boldsymbol{L}_{i,N,r}) = L^2_{\mathbb{C}} \times L^2_{\mathbb{C}} \times H^2_{\sharp,\mathbb{C}}$ generates an analytic strongly continuous semigroup that we denote by $e^{t\boldsymbol{L}_{i,N,r}}$.

In this section we are interested in proving that Hopf bifurcation occurs on the boundary of the set $\mathcal{P}$ (i.e., at the points $(N, r_{1,0}(N))$ and $(N, r_{2,0}(N))$ with $N \geq N_{2,0}$, where $r_{1,0}(N)$, $r_{2,0}(N)$ and $N_{2,0}$ are given by (3.14) and (3.15)) and in analyzing the stability of the bifurcated periodic solutions.

Note, that for $T_{\max}$ large,

$$N_{2,0} = \frac{\mu_I^2 + 3\mu_I\mu_V + \mu_V^2 + 2\sqrt{\mu_I\mu_T\mu_V(\mu_I + \mu_V)}}{\gamma\mu_I}\,\frac{1}{T_{\max}} + o(T_{\max}^{-1}).$$

Hence, $N_{2,0}$ is positive if $T_{\max}$ is large enough, let us say, if $T > T^1_{\max}(\mu_T, \mu_I, \mu_V, \alpha, \gamma) > T^0_{\max}(\mu_T, \mu_I, \mu_V, \alpha, \gamma)$ (see (2.6)). We assume hereafter that

$$T_{\max} \geq T^1_{\max}(\alpha, \gamma, \mu_I, \mu_T, \mu_V, N). \tag{4.1}$$

Here, differently from the previous sections, to avoid confusion we stress explicitly the dependence of the operators, numbers and sets that we consider on r. We do not stress the dependence on N since in the following discussions only the parameter r varies, N is (arbitrarily) fixed. In particular, we simply write r_1 and r_2 instead of $r_1(N)$ and $r_2(N)$.

Theorem 4.1. *Let $N \geq N_{2,0}$ be fixed. Under the hypothesis* (4.1)*, Hopf bifurcation occurs at the critical points $r = r_j$, $j = 1, 2$. More precisely,*

(i) *for any $\beta \in (0, 1)$, there exist $c_0 > 0$ and smooth functions $\hat{r}_j, \rho_j : (-\varepsilon_0, \varepsilon_0) \to \mathbb{R}$ and $\mathbf{X}_{\sharp,j} : (-\varepsilon_0, \varepsilon_0) \to C^{1+\beta}(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times L^2_\sharp) \cap C^\beta(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times H^2_\sharp)$ $(j = 1, 2)$ such that $\rho_j(0) = 1$, $\hat{r}_j(0) = r_j$, $\mathbf{X}_{\sharp,j}(0) = \mathbf{X}_i(r_j)$, $\mathbf{X}_{\sharp,j}(c)$ is not constant in time if $c \neq 0$ and its period is $2\pi\rho_j(x)/\omega_j$, where*

$$\omega = \sqrt{\alpha\gamma N + \frac{\alpha\gamma\mu_I N}{\mu_V} + \frac{\mu_V r_j}{\gamma N T_{\max}}(\mu_I + \mu_V)}, \qquad j = 1, 2.$$

(ii) *There exists $\delta > 0$ such that, if $\mathbf{X} \in C^{1+\beta}(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times L^2_\sharp) \cap C^\beta(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times H^2_\sharp)$ is a periodic solution to System* (1.1)-(1.3) (*where r is replaced by $\overline{r}$*) *with period $2\pi\overline{\rho}/\omega$, such that*

$$\|\mathbf{X} - \mathbf{X}_i(r_j)\|_{C^\beta(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times H^2_\sharp)} + \|\mathbf{X} - \mathbf{X}_i(r_j)\|_{C^{1+\beta}(\mathbb{R}, L^2_\sharp \times L^2_\sharp \times L^2_\sharp)} + |\overline{r} - r_j| + |1 - \overline{\rho}| \leq \delta_0,$$

for $j = 0$ or $j = 1$, then there exist $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$ and $t_0 \in \mathbb{R}$ such that $\overline{r} = \hat{r}_j$ and $\mathbf{X} = \mathbf{X}_{\sharp,j}(\varepsilon)$.

Proof. We limit ourselves to considering the case when $r = r_1$, the case $r = r_2$ being completely similar.

For r in some neighborhood of r_1, we set $\mathbf{u} = \mathbf{X} - \mathbf{X}_i(r)$, $s = r - r_1$ and write System (1.1)-(1.3) at the infected equilibrium as

$$\frac{d\mathbf{u}}{dt} = \mathfrak{F}(\mathbf{u}, s), \tag{4.2}$$

where

$$\begin{aligned}
\mathfrak{F}_1(\mathbf{u}, s) &= -\left(\frac{\mu_V(s + r_1)}{\gamma N T_{\max}} + \frac{\alpha\gamma N}{\mu_V}\right)u_1 - \frac{\mu_V}{N}u_3 - \frac{r_1 + s}{T_{\max}}u_1^2 - \gamma u_1 u_3;\\
\mathfrak{F}_2(\mathbf{u}, s) &= \left[\frac{\alpha\gamma N}{\mu_V} - \mu_T + (s + r_1)\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)\right]u_1 - \mu_I u_2 + \frac{\mu_V}{N}u_3 + \gamma u_1 u_3;\\
\mathfrak{F}_3(\mathbf{u}, s) &= \mu_I N u_2 + d_V \Delta u_3 - \mu_V u_3
\end{aligned}$$

Clearly, by the Sobolev embedding theorem, $\mathfrak{F}$ is a smooth function defined in $L^2 \times L^2 \times H^2_\sharp$.

Note that the derivative $\mathfrak{F}_{\mathbf{u}}(\mathbf{0}, 0)$ is the operator $\boldsymbol{L}_{i,r_1}$ in Proposition 3.3. More precisely,

$$\boldsymbol{L}_{i,r_1} = \begin{pmatrix} -\left(\frac{\mu_V r_1}{\gamma N T_{\max}} + \frac{\alpha\gamma N}{\mu_V}\right)Id & 0 & -\frac{\mu_V}{N}Id \\ \left[\frac{\alpha\gamma N}{\mu_V} - \mu_T + r_1\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)\right]Id & -\mu_I Id & \frac{\mu_V}{N}Id \\ 0 & N\mu_I Id & d_V\Delta - \mu_V Id \end{pmatrix}.$$

By Proposition 3.3, operator $\boldsymbol{L}_{i,r_1}$ is the generator of a strongly continuous analytic semigroup in $(L^2_{\mathbb{C}})^3$.

Let us prove that $\sigma(\boldsymbol{L}_{i,r_1})$ consists of eigenvalues with negative real part and a pair of purely imaginary and conjugate eigenvalues $\lambda_1(r_1)$ and $\lambda_2(r_1)$, which are simple eigenvalues and satisfy the transversality condition. Once checked, these properties will yield the assertion in view of [14, Thm. 9.3.3] (which deals with fully nonlinear problems but, of course, it applies also to the semilinear case).

Being rather long, we split the proof into four steps.

Step 1. Here, we prove that $\sigma(\boldsymbol{L}_{i,r_1})$ consists of eigenvalues with negative real part and a pair of purely imaginary and conjugate eigenvalues. For this purpose, we observe that, since $\mathcal{P}_k$ is properly contained in $\mathcal{P}_0$ for any $k = 1, \ldots, K_2$ (see Proposition 3.7), the pair $(N, r_1(N))$ belongs to $\mathcal{I} \setminus \mathcal{P}_k$ for any $k = 1, \ldots, K_2$. Therefore, from the results in Subsection 3.2 and Proposition 3.3, it follows that σ_{k,r_1} is contained in the halfplane $\{\lambda \in \mathbb{C} : \mathrm{Re}\,\lambda < 0\}$.

As far as σ_0 is concerned, Orlando formula (see e.g., [8, Chpt. XV]) shows that the Hurwitz determinant $D_{2,0}(r)$ (see (3.12)) factorizes as follows:

$$D_{2,0}(r) = -(\lambda_1(r) + \lambda_2(r))(\lambda_2(r) + \lambda_3(r))(\lambda_1(r) + \lambda_3(r)),$$

where $\lambda_1(r)$, $\lambda_2(r)$ and $\lambda_3(r)$ are the roots of the polynomial

$$\mathcal{D}_{0,r}(\lambda) = \lambda^3 + d_{1,0}(r)\lambda^2 + d_{2,0}(r)\lambda + d_{3,0}(r)$$

(see (3.8)) (i.e. the elements of σ_0). The point (r_1, N) lies on the boundary of $\mathcal{P}_0$. Hence, $D_{2,0}(r_1)$ vanishes, i.e.,

$$(\lambda_1(r_1) + \lambda_2(r_1))(\lambda_2(r_1) + \lambda_3(r_1))(\lambda_1(r_1) + \lambda_3(r_1)) = 0. \tag{4.3}$$

Since the coefficients of $\mathcal{D}_{0,r_1}$ are real and positive, at least one of the three roots $\lambda_1(r_1)$, $\lambda_2(r_1)$, $\lambda_3(r_1)$ (let us say $\lambda_3(r_1)$) is real and negative and the other two roots are either both negative or they are complex and conjugate. From (4.3) it follows that $\lambda_1(r_1)$ and $\lambda_2(r_1)$ are purely imaginary and conjugate.

Step 2. Let us prove that there exists a gap between $\sigma(\boldsymbol{L}_{i,r_1}) \setminus \{\lambda_1(r), \lambda_2(r)\}$ and the imaginary axis. We have to consider the set $\sigma_k = \sigma_{k,r_1}$ $(k = 1, 2, \ldots)$ which consists of the roots of the third-order polynomial $\mathcal{D}_{k,r_1}$ (see (3.8)). Indeed, as we have already remarked, $\lambda_3(r_1)$ is negative.

Write $\lambda = \mu - M$. If $\tilde{\lambda}$ is a root of the polynomial $\mathcal{D}_{k,r_1}$, then $\tilde{\mu} = \tilde{\lambda} + M$ is a root of the polynomial $p_{k,r_1}(\lambda) = \lambda^3 + \tilde{d}_{1,k}(r_1)\lambda^2 + \tilde{d}_{2,k}(r_1)\lambda + \tilde{d}_{3,k}(r_1)$, where

$$\begin{aligned}
&\tilde{d}_{1,k}(r_1) = d_{1,k}(r_1) - 3M,\\
&\tilde{d}_{2,k}(r_1) = d_{2,k}(r_1) - 2Md_{1,k}(r_1) + 3M^2,\\
&\tilde{d}_{3,k}(r_1) = d_{3,k}(r_1) - Md_{2,k}(r_1) + M^2 d_{1,k}(r_1) - M^3.
\end{aligned}$$

As it is easily seen

$$\begin{aligned}
&\tilde{d}_{1,k}(r_1) = d_V\lambda_k + o(\lambda_k),\\
&\tilde{d}_{3,k}(r_1) = \left[\frac{\alpha\gamma\mu_I N}{\mu_V} + \frac{\mu_I\mu_V r_1}{\gamma N T_{\max}} - \left(\mu_I + \frac{\alpha\gamma N}{\mu_V} + \frac{\mu_V r_1}{\gamma N T_{\max}}\right)M + M^2\right] d_V\lambda_k + o(\lambda_k),\\
&\tilde{d}_{1,k}(r_1)\tilde{d}_{2,k}(r_1) - \tilde{d}_{3,k}(r_1) = d_V^2\left(\mu_I + \frac{\alpha\gamma N}{\mu_V} + \frac{\mu_V r_1}{\gamma N T_{\max}} - 2M\right)\lambda_k^2 + o(\lambda_k^2),
\end{aligned}$$

as $k \to +\infty$. Hence, if we take M satisfying the inequalities

$$\begin{cases}
\dfrac{\alpha\gamma\mu_I N}{\mu_V} + \dfrac{\mu_I\mu_V r_1}{\gamma N T_{\max}} - \left(\mu_I + \dfrac{\alpha\gamma N}{\mu_V} + \dfrac{\mu_V r_1}{\gamma N T_{\max}}\right)M + M^2 > 0,\\[2ex]
\mu_I + \dfrac{\alpha\gamma N}{\mu_V} + \dfrac{\mu_V r_1}{\gamma N T_{\max}} - 2M > 0,
\end{cases}$$

then, for k sufficiently large (say $k \geq K_3 > K_2$), $\tilde{d}_{1,k}(r_1)$, $\tilde{d}_{3,k}(r_1)$ and $\tilde{d}_{1,k}(r_1)d_{2,k}(r_1) - \tilde{d}_{3,k}(r_1)$ are all positive. Hence, Routh-Hurwitz criterion applies and shows that the roots of p_{k,r_1} have negative real part of any $k \geq K_3$. As a byproduct, $\bigcup_{k \geq K_3} \sigma_{k,r_1} \subset \{\lambda \in \mathbb{C} : \mathrm{Re}\,\lambda < -M\}$.

Since $\bigcup_{1 \leq k < K_3} \sigma_{k,r_1}$ consists of finitely many eigenvalues with negative real part, up to replacing M with a smaller constant if needed, we can assume that $\bigcup_{1 \leq k} \sigma_{k,r_1} \subset \{\lambda \in \mathbb{C} : \mathrm{Re}\,\lambda < -M\}$.

Step 3. We now prove that the eigenvalues $\lambda_1(r_1)$ and $\lambda_2(r_1)$ are simple.

First, we prove that the resolvent operator $R(\lambda, \boldsymbol{L}_{i,r_1})$ has a simple pole at $\lambda_j(r_1)$ ($j = 1,2$). We limit ourselves to proving this property for the eigenvalue $\lambda_1(r_1)$, since for the other one the proof is completely similar.

From the proof of Proposition 3.3, we know that, for any $\lambda \in \rho(\boldsymbol{L}_{i,r_1})$ and any $\mathbf{f} \in (L^2_{\mathbb{C}})^3$,

$$R(\lambda, \boldsymbol{L}_{i,r_1})\mathbf{f} = \left(\sum_{k=0}^{+\infty} v_{1,k}(\lambda)\tilde{e}_k, \sum_{k=0}^{+\infty} v_{2,k}(\lambda)\tilde{e}_k, \sum_{k=0}^{+\infty} v_{3,k}(\lambda)\tilde{e}_k\right),$$

where $v_{j,k}(\lambda)$ ($j = 1,2,3$, $k \in \mathbb{N}$) are defined by (3.5)-(3.7).

Observe that

$$\mathcal{D}_{k,r_1}(\lambda) = \left[d_v\lambda^2 + \left(\mu_I d_V + \frac{\alpha\gamma d_V N}{\mu_V} + \frac{\mu_V r_1 d_V}{\gamma N T_{\max}}\right)\lambda + \frac{\alpha\gamma\mu_I d_V N}{\mu_V} + \frac{\mu_I\mu_V r_1 d_V}{\gamma N T_{\max}}\right]\lambda_k + d(\lambda, r_1),$$

where $d(\lambda, r_1)$ is independent of k, and it is smooth in λ.

As it is immediately seen the coefficient in front of λ_k does not vanish at $\lambda = \lambda_1(r_1)$. Hence, there exist a neighborhood U of $\lambda_1(r_1)$, $k_0 \in \mathbb{N}$ and a positive constant χ such that $|\mathcal{D}_{k,r_1}(\lambda)| \geq \chi\lambda_k$ for any $k \geq k_0$ and any λ in U. From (3.5)-(3.7) we thus deduce that

$$|v_{j,k}(\lambda)| \leq C(|f_{1,k}| + |f_{2,k}| + |f_{3,k}|),$$

for any $k \geq k_0$, $j = 1,2,3$ and $\lambda \in U$.

Since $\mathcal{D}_{k,r_1}(\lambda_1(r_1)) \neq 0$ for any $k \neq 0$, the previous estimate can be extended to any $k \geq 1$. Hence,

$$R(\lambda, \boldsymbol{L}_{i,r_1})\mathbf{f} = (v_{1,0}(\lambda), v_{2,0}(\lambda), v_{3,0}(\lambda)) + \left(\sum_{k=1}^{+\infty} v_{1,k}(\lambda)\tilde{e}_k, \sum_{k=1}^{+\infty} v_{2,k}(\lambda)\tilde{e}_k, \sum_{k=1}^{+\infty} v_{3,k}(\lambda)\tilde{e}_k\right),$$

where the second term in the previous splitting defines a function with values in $\mathcal{L}((L^2_{\mathbb{C}})^3)$ which is bounded in U.

The singularity of $R(\cdot, \boldsymbol{L}_{i,r_1})$ at $\lambda = \lambda_1(r_1)$ is due to the first term of the splitting. The results in Step 1 show that $\lambda \mapsto D_{0,r_1}(\lambda)$ has a simple zero at $\lambda = \lambda_1(r_1)$. It thus follows at once that the function $\lambda \mapsto ((\lambda - \lambda_1(r_1))v_{1,0}(\lambda), (\lambda - \lambda_1(r_1))v_{2,0}(\lambda), (\lambda - \lambda_1(r_1))v_{3,0}(\lambda))$ is bounded around $\lambda = \lambda_1(r_1)$.

Summing up, we have proved that the function $\lambda \mapsto (\lambda - \lambda_1(r_1))R(\lambda, \boldsymbol{L}_{i,r_1})$ is bounded around $\lambda = \lambda_1(r_1)$. Consequently, $R(\cdot, \boldsymbol{L}_{i,r_1})$ has a simple pole at $\lambda = \lambda_1(r_1)$, so that, by [14, Prop. A.2.2] $\lambda_1(r_1)$ is a semisimple eigenvalue of $\boldsymbol{L}_{i,r_1}$.

To conclude that it is, actually, a simple eigenvalue, we have to show that the eigenspace associated with $\lambda_1(r_1)$ is one dimensional. This property follows from recalling that $\mathcal{D}_{k,r_1}(\lambda_1(r_1)) \neq 0$ if $k \geq 1$. Hence, any eigenfunction associated with $\lambda_1(r_1)$ is a constant.

Step 4 . We now check the transversality condition. Observing that

$$\begin{aligned}
d_{1,0}(r_1) &= -(\lambda_1(r_1) + \lambda_2(r_1) + \lambda_3(r_1)) = \lambda_3(r_1),\\
d_{2,0}(r_1) &= \lambda_1(r_1)\lambda_2(r_1) + \lambda_1(r_1)\lambda_2(r_3) + \lambda_1(r_2)\lambda_2(r_3) = \lambda(r_1)\lambda(r_2),
\end{aligned}$$

from (3.9) and (3.10) we conclude that

$$\lambda_j(r_1) = (-1)^j\sqrt{\alpha\gamma N + \frac{\alpha\gamma\mu_I N}{\mu_V} + \frac{\mu_V r_1}{\gamma N T_{\max}}(\mu_I + \mu_V)}, \qquad j = 1,2,$$

and

$$\lambda_3(r_1) = -\mu_I - \mu_V - \frac{\mu_V r_1}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}.$$

By [12, Chpt. 20] the function $r \mapsto \lambda_1(r)$ is smooth in a neighborhood of r_1. Hence, differentiating the formula $(\lambda_1(r))^3 + d_{1,0}(r)(\lambda_1(r))^2 + d_{2,0}(r)\lambda_1(r) + d_{3,0}(r) = 0$, evaluating it at $r = r_1$ and then taking the real part, we get

$$\left(\frac{d}{dr}\mathrm{Re}\lambda_1\right)(r_1) = \frac{d'_{3,0}(r_1) - d'_{1,0}(r_1)d_{2,0}(r_1) - d_{1,0}(r_1)d'_{2,0}(r_1)}{2(d_{2,0}(r_1) + (d_{1,0}(r_1))^2)}.$$

The sign of $\left(\frac{d}{dr}\mathrm{Re}\lambda_1\right)(r_1)$ is the sign of $d'_{3,0}(r_1)-d'_{1,0}(r_1)d_{2,0}(r_1)-d_{1,0}(r_1)d'_{2,0}(r_1)$. A straightforward computation shows that

$$
\begin{aligned}
&d'_{3,0}(r_1)-d'_{1,0}(r_1)d_{2,0}(r_1)-d_{1,0}(r_1)d'_{2,0}(r_1)\\
=&\frac{1}{\gamma^2N^2T_{\max}^2}\Big[\gamma^2\mu_I\mu_T N^2T_{\max}^2-\gamma NT_{\max}\left(3\mu_I\mu_V^2+2\alpha\gamma\mu_I N+2\alpha\gamma\mu_V N+\mu_V^3+\mu_I^2\mu_V\right)\\
&\qquad\qquad -2\mu_V^3r_1-\mu_I\mu_V^2r_1\Big].
\end{aligned}
$$

Since

$$
r_1\sim\frac{1}{\mu_I\mu_V^3}\left(\mu_I\mu_T\mu_V^3+\alpha\gamma\mu_V^3N+\alpha\gamma\mu_I\mu_V^2N+\alpha\gamma\mu_I^2\mu_VN+\alpha^2\gamma^2\mu_VN^2+\alpha^2\gamma^2\mu_IN^2\right),
$$

as $T_{\max}\to+\infty$ (see (3.16)), $\left(\frac{d}{dr}\mathrm{Re}\lambda_1\right)(r_1)$ is positive if $T_{\max}$ is sufficiently large, as we are assuming. Hence, the transversality condition is satisfied. This completes the proof. □

Proposition 4.2. *The bifurcated periodic solutions provided by Theorem 4.1 are independent of the spatial variables, i.e., they are the same bifurcated periodic solutions of the following system of ODE's:*

$$
\frac{\partial T}{\partial t}=\alpha-\mu_TT+rT\left(1-\frac{T}{T_{\max}}\right)-\gamma VT, \tag{4.4}
$$

$$
\frac{\partial I}{\partial t}=\gamma VT-\mu_II, \tag{4.5}
$$

$$
\frac{\partial V}{\partial t}=N\mu_II-\mu_VV. \tag{4.6}
$$

Proof. In [6] it has been proved that System (4.4)-(4.6) exhibits a Hopf bifurcation at $r=r_j$ $(j=1,2)$. A branch of periodic solutions bifurcates from $\mathbf{X}_i(r_j)$ $(j=1,2)$. Clearly, such solutions are space independent. Moreover, a statement analogous to Theorem 4.1(ii) holds for the Hopf bifurcation associated with Problem (4.4)-(4.6), see [10, Thm. II, p. 16]. Therefore, up to replacing ε_0 with a smaller value, if needed, we can infer that, for any $\varepsilon\in(-\varepsilon_0,\varepsilon_0)$, $\mathbf{X}_\sharp(\varepsilon)$ coincides, up to a translation in the time variable, with one of the bifurcated periodic solutions in [6, Thm. 4.5]. This shows that any function $\mathbf{X}_\sharp(\varepsilon)$ is space independent. □

We can now prove the following theorem:

Theorem 4.3. *Suppose that* $T_{\max}\geq T_{\max}^{(3)}$*, where* $T_{\max}^{(3)}$ *depends on* α, γ, μ_I, μ_T *and* μ_V *(see the proof). Then, the following properties are satisfied.*

- (i) *If* $N<N_*$ *(where* N_* *is the first positive zero of the function* $\mathcal{H}$ *in* (4.13))*, then the periodic solution* $\mathbf{X}^1_\#(\varepsilon)$ *is orbitally asymptotically stable with asymptotic phase.*
- (ii) *For any* $N>0$*, the periodic solution* $\mathbf{X}^2_\#(\varepsilon)$ *is orbitally asymptotically stable with asymptotic phase.*

Proof. The arguments in Henry's book [11] (see also [3] in a more general situation) show that the stability of the bifurcated periodic solutions can be read on a Center Manifold. This allows to reduce our problem, which is set in a infinite dimensional Banach space, to a problem in a finite dimensional space.

To obtain this finite dimensional problem, we first need to determine the spectral projection associated to the eigenvalues $-\omega_ji$ and ω_ji $(j=1,2)$. As a general fact, such a projection is the sum of the spectral projections $P_{j,+}$, associated to the eigenvalue $i\omega_j$, and $P_{j,-}$, associated to the eigenvalue $-i\omega_j$. Since $i\omega_j$ and $-i\omega_j$ are simple eigenvalues (see Theorem 4.1), there exists a unique projection on the eigenspace relative to $i\omega_j$ which commutes with $\boldsymbol{L}_i$. Similarly, there exists a unique projection of the eigenspace relative to

$-i\omega_j$ which commutes with $\boldsymbol{L}_i$. Using these facts it is easy to check that

$$P_j\mathbf{v} = P_{j,+}\mathbf{v} + P_{j,-}\mathbf{v} = \kappa_j\left(\int_{\Omega_\ell}\mathbf{v}\overline{\boldsymbol{\psi}_{\boldsymbol{j}}}dxdy\right)\boldsymbol{\varphi}_{\boldsymbol{j}} + \overline{\kappa_j}\left(\int_{\Omega_\ell}\mathbf{v}\boldsymbol{\psi}_{\boldsymbol{j}}dxdy\right)\overline{\boldsymbol{\varphi}_{\boldsymbol{j}}},$$

for any $\mathbf{v} \in (L^2_{\mathbb{C}})^3$, where

$$\boldsymbol{\varphi}_{\boldsymbol{j}} = \left(\frac{\mu_V}{N(s_j - i\omega_j)}, \frac{\mu_V + i\omega_j}{\mu_I N}, 1\right), \qquad \boldsymbol{\psi}_{\boldsymbol{j}} = \left(-\frac{\xi_j}{s_j + i\omega_j}, 1, \frac{\mu_I - i\omega_j}{\mu_I N}\right)$$

and

$$s_j = -\frac{\mu_V r_j}{\gamma N T_{\max}} - \frac{\alpha\gamma N}{\mu_V}, \qquad \xi_j = \frac{\alpha\gamma N}{\mu_V} - \mu_T + \left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)r_j, \qquad \kappa_j^{-1} = (\boldsymbol{\varphi}_{\boldsymbol{j}}, \boldsymbol{\psi}_{\boldsymbol{j}})_2,$$

for $j = 1, 2$. In what follows we set $\boldsymbol{\varphi}_{\boldsymbol{j}} = (\varphi_{j,1}, \varphi_{j,2}, \varphi_{j,3})$ and $\boldsymbol{\psi}_{\boldsymbol{j}} = (\psi_{j,1}, \psi_{j,2}, \psi_{j,3})$.

As it is well known, P_j allows to split $(L^2_{\mathbb{C}})^3$ into the direct sum of the two subspaces $P_j((L^2_{\mathbb{C}})^3)$ and $(I - P_j)((L^2_{\mathbb{C}})^3)$ where $P_j((L^2_{\mathbb{C}})^3) = \{z\boldsymbol{\varphi} + w\overline{\boldsymbol{\varphi}} : z, w \in \mathbb{C}\}$ and $(I - P_j)((L^2_{\mathbb{C}})^3) = \{\mathbf{u} \in (L^2_{\mathbb{C}})^3 : (\mathbf{v}, \boldsymbol{\psi})_2 = (\mathbf{v}, \overline{\boldsymbol{\psi}})_2 = 0\}$. In particular, P_j maps $(L^2)^3$ into itself and allows us to split the space $(L^2)^3$ into the direct sum of the two subspaces $P_j((L^2)^3) = \{z\boldsymbol{\varphi} + \overline{z}\,\overline{\boldsymbol{\varphi}} : z \in \mathbb{C}\}$ and $(I - P_j)((L^2)^3) = \{\mathbf{u} \in (L^2)^3 : (\mathbf{u}, \boldsymbol{\psi})_2 = 0\}$.

Let us rewrite Problem (4.2) in the form

$$\frac{d\mathbf{u}}{dt} = \boldsymbol{L}_{i,r_j}\mathbf{u} + \mathcal{G}_{\boldsymbol{j}}(\mathbf{u}, s), \tag{4.7}$$

where

$$\begin{aligned}
\mathcal{G}_{\boldsymbol{j},\mathbf{1}}(\mathbf{u}, s) =& -\frac{\mu_V s}{\gamma N T_{\max}}u_1 - \frac{r_j + s}{T_{\max}}u_1^2 - \gamma u_1 u_3;\\
\mathcal{G}_{\boldsymbol{j},\mathbf{2}}(\mathbf{u}, s) =& s\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)u_1 + \gamma u_1 u_3;\\
\mathcal{G}_{\mathbf{3},\boldsymbol{j}}(\mathbf{u}, s) =& 0.
\end{aligned}$$

Splitting Problem (4.7) along $P_j((L^2)^3)$ and $(I - P_j)((L^2)^3)$, we see that any solution $\mathbf{u} \in C^1([0, a) \times (L^2)^3) \cap C([0, a) \times L^2 \times L^2 \times H^2_\sharp)$ to Problem (4.7), defined in some time domain $[0, a)$, can be identified with the pair of functions (z, w), with $z(t) \in \mathbb{C}$ and $\mathbf{w}(t) \in L^2 \times L^2 \times H^2_\sharp$ for any $t \in [0, a)$, which solves the system

$$\left\{\begin{aligned}
&\frac{dz}{dt} = i\omega_j z + \tilde{\mathcal{G}}_j(z, \overline{z}, \mathbf{w}, s), && (4.8)\\
&\frac{d\mathbf{w}}{dt} = \boldsymbol{L}_i\mathbf{w} + \mathcal{K}_{\boldsymbol{j}}(z, \overline{z}, \mathbf{w}, s), && (4.9)
\end{aligned}\right.$$

where

$$\begin{aligned}
\tilde{\mathcal{G}}_j(z, \overline{z}, \mathbf{w}, s) =& \kappa_j\left(\gamma\varphi_{j,1}(1 - \overline{\psi_{j,1}}) - \frac{(r_j + s)\varphi_{j,1}^2\overline{\psi_{j,1}}}{T_{\max}}\right)\ell^2 z^2\\
&+ \kappa_j\left(\gamma\overline{\varphi_{j,1}}(1 - \overline{\psi_{j,1}}) - \frac{(r_j + s)\overline{\varphi_{j,1}}^2\overline{\psi_{j,1}}}{T_{\max}}\right)\ell^2\overline{z}^2\\
&+ 2\kappa_j\left(\gamma(1 - \overline{\psi_{j,1}})\mathrm{Re}\,(\varphi_{j,1}) - \frac{(r_j + s)|\varphi_{j,1}|^2\overline{\psi_{j,1}}}{T_{\max}}\right)\ell^2 z\overline{z}\\
&+ \kappa_j\left[\int_{\Omega_\ell}\left(\gamma(1 - \overline{\psi_{j,1}})(\varphi_{j,1}w_3 + w_1) - \frac{2(r_j + s)\varphi_{j,1}\overline{\psi_{j,1}}}{T_{\max}}w_1\right)dxdy\right.\\
&\qquad\left. - \frac{\mu_V s\varphi_{j,1}\overline{\psi_{j,1}}}{\gamma N T_{\max}}\ell^2 + s\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right)\varphi_{j,1}\ell^2\right]z
\end{aligned}$$

$$
\begin{aligned}
&+ \kappa_j \left[\int_{\Omega_\ell} \left(\gamma(1 - \overline{\psi_{j,1}})(\overline{\varphi_{j,1}} w_3 + w_1) - \frac{2(r_j + s)\overline{\varphi_{j,1}}\,\overline{\psi_{j,1}}}{T_{\max}} w_1 \right) dxdy \right. \\
&\qquad \left. - \frac{\mu_V s \overline{\varphi_{j,1}}\,\overline{\psi_{j,1}}}{\gamma N T_{\max}} \ell^2 + s\left(1 - \frac{\mu_V}{\gamma N T_{\max}}\right) \overline{\varphi_{j,1}} \ell^2 \right] \overline{z} \\
&+ \kappa_j \int_{\Omega_\ell} \left(\gamma(1 - \overline{\psi_{j,1}}) w_3 - \frac{(r_j + s)\overline{\psi_{j,1}}}{T_{\max}} w_1 - \frac{\mu_V s(\overline{\psi_{j,1}} + 1)}{\gamma N T_{\max}} + s \right) w_1 dxdy;
\end{aligned}
$$

$$\boldsymbol{\mathcal{K}_j}(z, \overline{z}, \mathbf{w}, s) = \boldsymbol{\mathcal{G}_j}(z, \overline{z}, \mathbf{w}, s) - 2\mathrm{Re}\,(\tilde{\mathcal{G}}_j(z, \overline{z}, \mathbf{w}, s)\boldsymbol{\varphi}),$$

for $j = 1, 2$. Modulo the identification of $P_j((L^2)^3)$ with the set $\{(z, \overline{z}) : z \in \mathbb{C}\}$, the Center Manifold for System (4.8)-(4.9) is the graph of a smooth function $\boldsymbol{\Upsilon_j}$ of the variable $(z, \overline{z}, s)$, defined in a neighborhood of zero with values in $(I - P_j)((L^2)^3)$.

The equation to be analyzed, to understand the stability of the bifurcated solutions $\mathbf{X}_\sharp(\varepsilon)$, is therefore the following one:

$$\frac{dz}{dt} = i\omega_j z + \tilde{\mathcal{G}}_j(z, \overline{z}, \boldsymbol{\Upsilon_j}(z, \overline{z}, s), s) =: g_j(z, \overline{z}, s). \tag{4.10}$$

This ODE can be studied with classical methods (see e.g., [10, Chpts. 1 & 2]). One needs to expand the nonlinearity g_j around 0 as

$$g_j(z, \overline{z}, 0) = \sum_{2 \le h+k \le 3} \frac{g_{hk}^{(j)}}{h!k!} z_h \overline{z}_k + o(|z|^4).$$

The coefficients $g_{hk}(s)$ are fundamental to determine the stability of the periodic solutions to (4.10). In fact, such solutions are stable if and only if $\mathrm{Re}\, c_1(r_j) < 0$, where (see e.g., [10, p. 90])

$$c_1(r_j) = \frac{i}{2\omega_j}\left(g_{20}^{(j)} g_{11}^{(j)} - 2|g_{11}^{(j)}|^2 - \frac{1}{3}|g_{02}^{(j)}|^2 \right) + \frac{1}{2} g_{21}^{(j)}.$$

To expand g around the origin, one first needs to expand the function $\Upsilon(\cdot, \cdot, 0)$ around $(0, 0)$. Since this function is smooth, we can expand it as

$$\boldsymbol{\Upsilon_j}(z, \overline{z}, 0) = \mathbf{a}_1^{(j)} z + \mathbf{a_2}^{(j)} \overline{z} + \mathbf{a_3}^{(j)} z^2 + \mathbf{a_4}^{(j)} z\overline{z} + \mathbf{a_5}^{(j)} z^2 + O(|z|^3).$$

Replacing $\mathbf{u}(t) = z(t)\boldsymbol{\varphi} + \overline{z(t)}\overline{\boldsymbol{\varphi}} + \boldsymbol{\Upsilon}(z(t), \overline{z(t)})$ into System (4.8)-(4.9), expanding

$$\boldsymbol{\mathcal{K}_j}(z, \overline{z}, \mathbf{w}, 0) = \boldsymbol{\mathcal{K}_{j,1}} z^2 + 2\boldsymbol{\mathcal{K}_{j,2}} z\overline{z} + \overline{\boldsymbol{\mathcal{K}_{j,1}}}\, \overline{z}^2 + O(|z||w|) + O(|w|^2),$$

and observing that

$$\frac{d}{dt}\mathbf{w}(t) = \frac{\partial \boldsymbol{\Upsilon_j}}{\partial z}(z(t), \overline{z(t)}) z'(t) + \frac{\partial \boldsymbol{\Upsilon_j}}{\partial \overline{z}}(z(t), \overline{z(t)}) \overline{z'(t)},$$

an asymptotic analysis reveals that

$$\boldsymbol{\Upsilon_j}(z, \overline{z}, 0) = z^2(2i\omega_j - \boldsymbol{L}_{i,r_j})^{-1} \boldsymbol{\mathcal{K}_{j,1}} - 2z\overline{z} \boldsymbol{L}_{i,r_j}^{-1} \boldsymbol{\mathcal{K}_{j,2}} + \overline{z}^2(-2i\omega_j - \boldsymbol{L}_{i,r_j})^{-1} \overline{\boldsymbol{\mathcal{K}_{j,1}}} + O(|z|^3).$$

where

$$\boldsymbol{\mathcal{K}_{j,1}} = \begin{pmatrix} \left(\dfrac{r_j \varphi_{j,1}^2}{T_{\max}} + \gamma \varphi_{j,1} \right) \left(2\ell^2 \mathrm{Re}\,(\kappa_j \varphi_{j,1} \overline{\psi_{j,1}}) - 1 \right) - 2\gamma \ell^2 \varphi_{j,1} \mathrm{Re}\,(\kappa_j \varphi_{j,1}) \\ 2\ell^2 \left(\dfrac{\varphi_{j,1}^2 r_j}{T_{\max}} + \gamma \varphi_{j,1} \right) \mathrm{Re}\,(\kappa_j \varphi_{j,2} \overline{\psi_{j,1}}) + \gamma \varphi_{j,1} \left(1 - 2\ell^2 \mathrm{Re}\,(\kappa_j \varphi_{j,2}) \right) \\ 2\ell^2 \left(\dfrac{\varphi_{j,1}^2 r_j}{T_{\max}} + \gamma \varphi_{j,1} \right) \mathrm{Re}\,(\kappa_j \overline{\psi_{j,1}}) - 2\gamma \ell^2 \varphi_{j,1} \mathrm{Re}\,(\kappa_j) \end{pmatrix},$$

$$\boldsymbol{\mathcal{K}_{j,2}} = \begin{pmatrix} \left(\dfrac{r_j|\varphi_{j,1}|^2}{T_{\max}} + \gamma\mathrm{Re}\,(\varphi_{j,1})\right)\left(2\ell^2\mathrm{Re}\,(\kappa_j\varphi_{j,1}\overline{\psi_{j,1}}) - 1\right) - 2\gamma\ell^2\mathrm{Re}\,(\varphi_{j,1})\mathrm{Re}\,(\kappa_j\varphi_{j,1}) \\ 2\ell^2\left(\dfrac{r_j|\varphi_{j,1}|^2}{T_{\max}} + \gamma\mathrm{Re}\,(\varphi_{j,1})\right)\mathrm{Re}\,(\kappa_j\varphi_{j,2}\overline{\psi_{j,1}}) + \gamma\mathrm{Re}\,(\varphi_{j,1})\left(1 - 2\ell^2\mathrm{Re}\,(\kappa_j\varphi_{j,2})\right) \\ 2\ell^2\left(\dfrac{r_j|\varphi_{j,1}|^2}{T_{\max}} + \gamma\mathrm{Re}\,(\varphi_{j,1})\right)\mathrm{Re}\,(\kappa_j\overline{\psi_{j,1}}) - 2\gamma\ell^2\mathrm{Re}\,(\varphi_{j,1})\mathrm{Re}\,(\kappa_j) \end{pmatrix}.$$

Note that, since $\boldsymbol{\mathcal{K}_j}(z,\overline{z},\mathbf{w}) \in (I-P_j)((L^2)^3)$ for any $z \in \mathbb{C}$ and $\mathbf{w} \in (I-P_j)((L^2)^3)$, $\boldsymbol{\mathcal{K}_{j,1}}$, $\boldsymbol{\mathcal{K}_{j,2}}$ and $\overline{\boldsymbol{\mathcal{K}_{j1}}}$ belong to $(I-P_j)((L^2_{\mathbb{C}})^3)$ and the operators $\pm i\omega - \boldsymbol{L}_{i,r_j}$ are invertible on $(I-P_j)((L^2_{\mathbb{C}})^3)$.

Now a long but straightforward computation shows that

$$\begin{aligned} g_{20}^{(j)} &= -\frac{2r_j\kappa_j\varphi_{j,1}^2\overline{\psi_{j,1}}\ell^2}{T_{\max}} + 2\gamma\kappa_j\varphi_{j,1}(\overline{\psi_{j,2}} - \overline{\psi_{j,1}})\ell^2, \\ g_{11}^{(j)} &= -\frac{2r_j\kappa_j|\varphi_{j,1}|^2\overline{\psi_{j,1}}\ell^2}{T_{\max}} + 2\gamma\kappa_j\ell^2(\overline{\psi_{j,2}} - \overline{\psi_{j,1}})\mathrm{Re}(\varphi_{j,1}), \\ g_{02}^{(j)} &= -\frac{2r_j\overline{\varphi_{j,1}}^2\overline{\kappa_j\psi_{j,1}}\ell^2}{T_{\max}} + 2\gamma\kappa\overline{\varphi_{j,1}}(\overline{\psi_{j,2}} - \overline{\psi_{j,1}})\ell^2, \\ g_{21}^{(j)} &= -\frac{2r_j\kappa_j\overline{\psi_{j,1}}\ell^2}{T_{\max}}\Big[(\overline{\varphi_{j,1}}(2i\omega_j - \boldsymbol{L}_{i,r_j})^{-1}\boldsymbol{\mathcal{K}_{j,1}})_1 - 2\varphi_{j,1}(\boldsymbol{L}_{i,r_j}^{-1}\boldsymbol{\mathcal{K}_{j,2}})_1\Big] \\ &\quad + \gamma\kappa_j(\overline{\psi_{j,2}} - \overline{\psi_{j,1}})\ell^2\Big[\overline{\varphi_{j,1}}((2i\omega_j - \boldsymbol{L}_{i,r_j})^{-1}\boldsymbol{\mathcal{K}_{j,1}})_3 + ((2i\omega_j - \boldsymbol{L}_{i,r_j})^{-1}\boldsymbol{\mathcal{K}_{j,1}})_1 \\ &\qquad - 2\varphi_{j,1}(\boldsymbol{L}_{i,r_j}^{-1}\boldsymbol{\mathcal{K}_{j,2}})_3 - 2(\boldsymbol{L}_{i,r_j}^{-1}\boldsymbol{\mathcal{K}_{j,2}})_1\Big], \end{aligned}$$

where $(\cdot)_k$ denotes the k-th component of the vector in brackets.

Since an explicit computation of these coefficients for any value of $T_{\max}$ is uneasy, and we are interested in large (enough) values of $T_{\max}$, as in [6, Sec. 4.3] we determine the sign of $\mathrm{Re}\,c_1(r_j)$ via an asymptotic analysis as $T_{\max} \to +\infty$. We get

$$\mathrm{Re}\,c_1(r_1) = \frac{\gamma\mu_V^2}{\mathcal{D}(N)}\mathcal{H}(N) + o(1), \qquad \mathrm{Re}\,c_1(r_2) = -\frac{50(\mu_I+\mu_V)^3}{\mu_I^2N^2T_{\max}^2} + o(T_{\max}^{-2}), \tag{4.11}$$

where $\mathcal{D}(N)$ and $\mathcal{H}(N)$ are respectively given by

$$\begin{aligned} \mathcal{D}(N) =& 2\alpha(\mu_I\mu_V + \mu_V^2 + \alpha\gamma N)(\mu_I^2\mu_V^2 + 2\mu_I\mu_V^3 + 6\alpha\gamma\mu_I\mu_V N + \mu_V^4 + 6\alpha\gamma\mu_V^2 N + \alpha^2\gamma^2N^2) \\ & \times(\alpha^2\gamma^2N^2 + 3\alpha\gamma\mu_I\mu_V N + 3\alpha\gamma\mu_V^2N + \mu_I^2\mu_V^2 + 2\mu_I\mu_V^3 + \mu_V^4) \\ & \times(\mu_I^2\mu_V + 2\mu_I\mu_V^2 + \mu_I\mu_V + \mu_V^3 + \mu_V^2 + \alpha\gamma\mu_V N)N, \end{aligned} \tag{4.12}$$

$$\begin{aligned} \mathcal{H}(N) =& 3\alpha^5\gamma^5(\mu_I+\mu_V)^2N^5 - \alpha^4\gamma^4\mu_V(\mu_I+\mu_V)(12\mu_I^2 + 35\mu_I\mu_V + 12\mu_V^2)N^4 \\ & - \alpha^3\gamma^3\mu_V^3(26\mu_I^4 + 151\mu_I^3\mu_V + 247\mu_I^2\mu_V^2 + 151\mu_I\mu_V^3 + 26\mu_V^4)N^3 \\ & - \alpha^2\gamma^2\mu_V^3(\mu_I+\mu_V)(12\mu_I^4 + 85\mu_I^3\mu_V + 134\mu_I^2\mu_V^2 + 85\mu_I\mu_V^3 + 12\mu_V^4)N^2 \\ & - \alpha\gamma\mu_V^4(\mu_I+\mu_V)^2(\mu_I^4 + 13\mu_I^3\mu_V + 35\mu_I^2\mu_V^2 + 13\mu_I\mu_V^3 + \mu_V^4)N - 4\mu_I^2\mu_V^7(\mu_I+\mu_V)^3. \end{aligned} \tag{4.13}$$

Whereas $\mathcal{D}(N)$ is always positive, the sign of $\mathcal{H}(N)$ depends on N. Since $\mathcal{H}(0) < 0$ and $\lim_{N\to+\infty}\mathcal{H}(N) = +\infty$, the function $\mathcal{H}$ has at least a positive zero. We define by N_* the (first) positive zero of $\mathcal{H}$. Therefore, $\mathcal{H}(N) < 0$ for $0 \le N < N_*$. We thus conclude that, for $T_{\max}$ large enough (let us say $T_{\max} > T_{\max}^{(3)} > T_{\max}^{(2)}$, which depends on α, γ, μ_I, μ_T and μ_V), $\mathrm{Re}\,c_1(r_1) < 0$ for any $0 < N < N_*$, whereas $\mathrm{Re}\,c_1(r_2) < 0$ for any $N > 0$. This completes the proof. □

5. **Numerical results**

In order to show the stability of the infected steady state numerically, we can fix $N = 300$, start from the value $r_{crit,0} = 0.05625$, increase the logistical parameter r monotonically until a critical condition is reached such that any further change would result in instability, other parameters can be found in Table 1. We present the graphs of numerical solution of the system (1.1)-(1.3) and the trajectory of the solution in the three-dimensional T-V-I space. Initial data are $T_0 = T_u + \varepsilon(\sin x \cos y),\ I_0 = 0.0,\ V_0 = 0.0185$. Some figures assure that this solution approaches the limit cycle in the instability subdomain $\mathcal{P}$. In Figure 7 corresponding to the subdomain $\mathcal{P}$, the solution approaches the periodic orbit.

APPENDIX A. EIGENVALUES OF THE LAPLACE OPERATOR WITH PERIODIC BOUNDARY CONDITIONS

Let A be the realization of the Laplace operator Δ in $L^2_{\mathbb{C}}$, with $H^2_{\sharp,\mathbb{C}}$ as a domain. The following is a well-known result. Nevertheless, for the reader's convenience we provide a short proof.

Theorem A.1. *A is a sectorial operator and its spectrum $\sigma(A)$ is a countable set of semisimple eigenvalues. More precisely,*

$$\sigma(A) = \left\{-\frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2) : k_1, k_2 \in \mathbb{N}\right\}. \tag{A.1}$$

Proof. Fix $\lambda \in \mathbb{C}$, $f \in L^2_{\mathbb{C}}$ and consider the resolvent equation

$$\lambda u - Au = f. \tag{A.2}$$

Denote by e_h the function defined by

$$e_h(t) = \exp\left(\frac{2h\pi t}{\ell}i\right), \qquad t \in \mathbb{R},$$

for any $h \in \mathbb{Z}$. Then, the functions $(x, y) \mapsto e_h(x)e_k(y)$ are an orthogonal basis of $L^2_{\mathbb{C}}$. Hence, any function $g \in L^2_{\mathbb{C}}$ can be expanded into a Fourier series as follows:

$$g(x,y) = \sum_{k_1,k_2\in\mathbb{N}}\left(\frac{1}{\ell^2}\int_{\Omega_\ell} u(x,y)e_{-k_1}(x)e_{-k_2}(y)dxdy\right)e_{k_1}(x)e_{k_2}(y) =: \sum_{k_1,k_2\in\mathbb{N}} u_{k_1,k_2}e_{k_1}(x)e_{k_2}(y),$$

for almost every $(x, y) \in \Omega_\ell$. Multiplying both sides of (A.2) by $e_{k_1}(x)e_{k_2}(y)$ and integrating over Ω_ℓ, it thus follows that, if $u \in H^2_{\sharp,\mathbb{C}}$, then the Fourier coefficients of u solves the infinitely many equations

$$\lambda\ell^2 u_{k_1,k_2} + 4\pi^2(k_1^2 + k_2^2)u_{k_1,k_2} = \ell^2 f_{k_1,k_2}.$$

These equations are uniquely solvable if and only if $\lambda \neq -\frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)$ and, in this case, we have

$$u_{k_1,k_2} = \frac{f_{k_1,k_2}}{\lambda + \frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)}.$$

A straightforward computation shows that the function

$$u(x,y) = \sum_{k_1,k_2\in\mathbb{N}} \frac{f_{k_1,k_2}}{\lambda + \frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)} e_{k_1}(x)e_{k_2}(y), \quad (x,y) \in \Omega_\ell$$

is in $D(A)$ and, actually, solves the resolvent equation, when $\lambda \neq -\frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)$ for any $k_1, k_2 \in \mathbb{N}$. We have so proved that $\sigma(A)$ is given by (A.1).

It is immediate to check that $\sigma(A)$ consists of eigenvalues only. Moreover, if $\operatorname{Re}\lambda > 0$, we can estimate

$$\|R(\lambda, A)f\|^2_{L^2(\Omega_\ell)} = \sum_{k_1,k_2\in\mathbb{N}} \frac{|f_{k_1,k_2}|^2}{\left|\lambda + \frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)\right|^2} \leq \frac{1}{|\lambda|^2}\sum_{k_1,k_2\in\mathbb{N}}|f_{k_1,k_2}|^2 = \frac{1}{|\lambda|^2}\|f\|^2_{L^2(\Omega_\ell)}.$$

Proposition 2.3.1 in [14] implies that A is sectorial in $L^2(\Omega_\ell)$.

Finally, we show that all the eigenvalues of A are semisimple. For this purpose, let us fix one of such eigenvalues λ_0 and let $H = \{(k_1, k_2) \in \mathbb{N}^2 : \lambda_0 = -\frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)\}$. Then,

$$\begin{aligned}(\lambda - \lambda_0)R(\lambda, A)f(x,y) &= \sum_{k_1,k_2\in H} f_{k_1,k_2}e_{k_1}(x)e_{k_2}(y) + \sum_{k_1,k_2\notin H}\frac{\lambda - \lambda_0}{\lambda + \frac{4\pi^2}{\ell^2}(k_1^2 + k_2^2)} f_{k_1,k_2}e_{k_1}(x)e_{k_2}(y)\\ &=: Pf(x,y) + (\lambda - \lambda_0)D_\lambda f(x,y).\end{aligned}$$

Clearly, P is the spectral projection on the eigenspace corresponding to the eigenvalue λ_0. On the other hand, D_λ is a bounded operator in $L^2_{\mathbb{C}}$ uniformly with respect to $\lambda \in B(\lambda_0, 2\pi^2/\ell^2)$. Indeed, if $(k_1, k_2) \notin H$ and λ is as above, then

$$\left|\frac{4\pi^2}{\ell^2}(k_1^2+k_2^2)+\lambda\right| \geq \left|\frac{4\pi^2}{\ell^2}(k_1^2+k_2^2)+\lambda_0\right| - |\lambda-\lambda_0| \geq \frac{4\pi^2}{\ell^2} - |\lambda-\lambda_0| \geq \frac{2\pi^2}{\ell^2}.$$

Thus,

$$\|D_\lambda f\|^2_{L^2(\Omega_\ell)} \leq \frac{\ell^4}{4\pi^4}\sum_{(k_1,k_2)\notin H}|f_{k_1,k_2}|^2 \leq \frac{\ell^4}{4\pi^4}\|f\|^2_{L^2(\Omega_\ell)},$$

i.e., D_λ is bounded, uniformly with respect to $\lambda \in B(\lambda_0, 2\pi^2/\ell^2)$. These results imply that λ_0 is a semisimple eigenvalue of A. Note that the eigenspace corresponding to λ_0 is one-dimensional if and only if H is a singleton. In this case, λ_0 is a simple eigenvalue of A. More precisely, the geometric multiplicity of the eigenvalue $\lambda = \frac{4\pi^2}{\ell^2}(k_1^2+k_2^2)$ is given by $m_\lambda = 4\prod_{i=1}^m(r_i+1)$, where the coefficients r_i are given by the following decomposition of $k_1^2+k_2^2$ in primes

$$k_1^2+k_2^2 = 2^\alpha\prod_{i=1}^m p_i^{r_i}\prod_{j=1}^n q_j^{s_j},$$

with p_i being primes of the form $4t+1$, and q_j being primes of the form $4t+3$ (see [9]). □

The following classical result on Sturm-Liouville problems is the key tool to prove Theorem 2.1(iv).

Corollary A.2. *Let d and μ be, respectively, a positive constant and a bounded measurable function. Further, let $B : H^2_\sharp \to L^2$ be the operator defined by $Bu = d\Delta u - \mu u$ for any $u \in H^2_\sharp$. Then, the spectrum of B consists of eigenvalues only. Moreover, its maximum eigenvalue $\lambda_{\max}$ is given by the following formula:*

$$\lambda_{\max} = -\inf_{\psi\in H^1_\sharp,\psi\not\equiv 0}\left\{\frac{d\int_{\Omega_\ell}|\nabla\psi|^2dx + \int_{\Omega_\ell}\mu\psi^2dx}{\int_{\Omega_\ell}\psi^2dx}\right\}. \tag{A.3}$$

Finally, the eigenspace corresponding to the eigenvalue $\lambda_{\max}$ is one dimensional and contains functions which do not change sign in $\overline{\Omega_\ell}$.
